The best 10 meter antenna that i have used has been the Outbacker Perth + it outpreformed my Wilson antennas hands down and covers all of the 10 meter band and has some gain in it. It is priceeeeeeeeee thow.
It also covers most all of the other bands to 2 through 80 meters but is real hot on 10 & 12 meters. Great antenna!

Hi Dick,
Don;t know about the automatic control but have been using the manual control for about 6 months with my 706 and the ATAS 100 and think it is a great setup, best that i have used so far, works like a Champ! The company makes some real good products, use two of there DSP speakers they also work Great, better than most DSP units that come in radios.

J&V:

Well, strictly speaking, fractals are not frauds.

Fractal antennas may in fact have some good uses.

But some/most of the outrageous claims made for fractal antennas are indeed fradulent!

Those TV ads showing the "under battery" antenna, with the girl stating that her calls are more "clear" with the antenna are just plain stupid.

> vee by itself?

Neither will be high enough to be too directive. The 80 a little more so than the 160. Having the legs sloped or not will have little difference on the pattern. The height means more. On 160m the extra ground losses from having the ends low at 10 ft, would give a definite advantage to a flat dipole. I always prefer a flattop dipole if possible when used on the low bands. Get the whole thing as high as you can. You can tell a difference in the overall performance. I use the same thing here except I feed with coax and use no tuner normally. Adding the 80 legs will make the 80 m pattern more dipole like with less broadside gain than the normal two half waves in phase you would have with the 160 antenna on 80m. But if the 160 legs are fairly sloped the gain on 80 wouldn't be too high. Either would work, but I bet 80 will be better with the extra 80 legs on there than the 160 antenna alone. Should work out ok. MK

> So, Mark, getting back to my inductance to ground...any more thoughts on that?
>

I'm not sure. I've never run one grounded, or used a coil to ground as lightning protection. The tricky part is it's going to be multi band with different feed systems as a 1/4 and 1/2 wave etc. You would need a L/C circuit to match for a half wave. Usually, this type of feed would be at dc ground. But the feed for 80 and 160 likely would not be. So if you wanted to add a choke , it would probably be for 160/80. If you just wanted a way to dc ground the antenna when not in use, maybe you could switch it for 40m with it grounded match? It probably wouldn't matter much when in use as I doubt you will be operating in storms. Whatever you end up with, with those number of radials it should do well. That thing should really play on 80m. Won't be bad on 160 if you got it set up with fairly low loss loading. MK

HF Antenna Advice Needed!

I am a homeowner living on a small 70' x 100' lot. I have no tower or trees. I am currently using a Van Gorden Engineering All Band Shorty (70 feet overall length) for 10 thru 80 meters. It is about 10 feet off the ground. It's ok except for 40M - that's kinda weak. What are your opinions about this antenna? Is there a better HF shorty antenna out there? Would I be better off with individual dipoles for each band? Is vertical the way to go? I know there is a vast wealth of knowledge out there. Please advise how I can make the most of my limited space and resouces.

Thanks a million,
John N7MTB

Hi John -- for horizontal antennas -- ya got to get em up at least half a wavelength - otherwise you squirt energy primarily upwards -- not good for DX. Try a vertical -- a half wave end fed (Cushcraft) works well for me -- mounted 8 feet off the ground and 27 feet high. Woked mucho DX with it -- brag brag. Mine covers all bands 40M thru 10M.

No dipole will perform very well on 40m when it is 10 feet off the ground.
In 1952 when I raised my 40m dipole from 10 feet to 20 feet the difference
was dramatic. If you can get that Shorty up around 30 feet, you will have
a pretty good 40m antenna and it will perform well on the higher bands.

Try a two-way radio shop in your area. It won't be the cheapest, but they should be able to handle most antenna jobs. Or, their tower person may be willing to take on side job if the business isn't interested in ham work.

John

If you want a relatively simple all - HF band antenna that will work DX, you'll have to go up since you don't have the space to go out.

I would get an all band vertcal, such as the Butternut HFV series, and get the base of it as high as possible (50-60 feet). I would than slope radial wires symmetrically down from the base at no more than a 45 degree angle (6-8 for each band at 50 feet up, you can make multi band radials from TV ribbon). The ARRL Antenna book discusses # of radials vs height of base.This will be a multiband ground plane which should give excellent results most bands with a single coax feed.

See the ARRL antenna compednium (#4 or # 5 I think). A fellow used this scheme using trap radials and reported excellent results.

An alternatrive wire antenna for your lot size would be the inverted L. The late Doug DeMaw had excellent results on the HF bands with this antenna. It is also in one of the ARRL antenna compedniums but I can't recall which one. It will require a greater # of longer ground mounted radials and an antenna tuner for all band use.

Anything the same length is going to perform about the same.

But use a Pryme RD-98SMA and its 17" - and you will dramatically
improve 2M and 440 performance. Made from super-thin "piano wire-like"
material, you can actually "fold" the unit into a 6" coil for storage
in a plastic sandwich bag.

And although it's not supposed to work on 220, I am having very good
results using it on my Kenwood TH-F6A, too!

Lin:
Part of the problem is you have the name partly transposed, the other is they were bought out, and then the combination company filed for bankruptcy.

The correct name is Ocean Applied Research (OAR). They were bought by TechComm, of whom I have lost track. Try a Google search for TechComm and see if anything useful pops up. If not, email me directly and I will see if I still have any old TechComm literature in the basement archives.

Roy Lewallen wrote:
"I disagree that radiation resistance is the purpose of antenna design."

My aim in in antenna design is not the production of loss resistance!

The directional patterns seen in the 1955 edition of Terman`s "Electronic and Radio Engineering" on page 864 for the elementary doublet antenna and on page 907 for the small (say less than 0.1 wavelangth diameter) loop antenna are seen to be identical. They are both figure-8 patterns.

The impedance of a tiny doublet is nearly an open circuit. A tiny loop is nearly a short. Impedance and directional characteristics are not close relatives.

A folded antenna element with similar duplex conductors has 4 times the feedpoint impedance of the single open-circuit 1/4-wave monopole or 1/2-wave dipole.

Gain and directivity are different sides of the same coin. Gain and directivity are nearly identical whether the antenna`s elements are folded or not.

I`ve used a folded dipole with 3 wires to get 9 times the impedance of the simple 1/2-wave dipole so as to nearly match my 600-ohm transmission line. The folded dipole was my reference antenna for proving a new shortwave broadcast array. The folded dipole performance was the same as a simple dipole as required for valid gain measurements. The important thing was to deliver the same power to all antennas for comparison. The voltage to current ratio at the antenna feedpoint was irrelevant for an antenna if the power was delivered to the antenna. The power into the measured and reference antennas had to be the same.

The point of folding antennas is matching the feedline.

The same current through the same loss resistance produces the same loss. I think Roy did an excellent job of showing the same current into the ground under either a straight or folded grounded antenna element. Transmission line loss can be reduced by a match to the antenna.

Best regards, Richard Harrison, KB5WZI

My Comet SMA-503 is only 8 1/2 " long, an inch or so more than the stock VX5 antenna, yet its performance is noticeably better on both 2M and 440, 440 being substantially more effective. Length is important, but so is an effective match to the HT. Comet seems to do it better than Yaesu.

No surprise, it's 'way too low.
>
>What are your opinions about
> this antenna?
>
I took a dim view of G5RVs for years until I tossed one up for Field
Day this past June. It worked quite well at the 20/15m cw station. The
thing only cost $25 and it was 100% plug 'n play right outta the box,
I've grudgingly developed at least some respect for the things given a
lazy man's approach to HF wire antennas AND a radio with a capable
autotuner. Which we had.
>
>
>Is there a better HF shorty antenna out there?
>
>
Yes, a 100 foot non-resonant open line fed dipole/inverted vee. The
fundamental problem with G5RVs is that they are nothing more than
"fudged" coax-fed versions of the real thing. The net result is that

they present manageable swrs within only a few of the ham bands. A
real non-resonant open-line fed dipole can be operated on any
frequency with a 1:1 swr IF you have a decent balanced antenna tuner.
An autotuner will not be able to cope with the range of mismatches a
random length dipole exhibits at it's feedpoint. Which means you would
have to buy or build a decent balanced manual antenna tuner. Those are
not $25 whether you buy or build one. I don't know of any real
balanced tuners you can just go out and purchase today unless you pick
up an old Johnson Matchbox.
>
>
The tradeoff here is complete flexibility with low losses but which
require money and work versus cheap, dirty and convenient G5RVs with
very limited band coverage. Ya takes yer pick and lives with it.
>
>
>Would I be
> better off with individual dipoles for each band?
>
If you can put up coax-fed dipoles for every band you operate the
answer is yes.
>
>
>Is vertical the way to go?
>
>
I've tried several HF verticals over the years but I have yet to have
one perform as well as a simple dipole at a reasonable height on both
the dx and local "circuits". Plus verticals inhale a lot more
electrical noise than do dipoles. Your mileage may vary.
>
>
> I know there is a vast wealth of knowledge out there. Please advise how I

Parting shot: If I were you I'd concentrate first on getting that G5RV
up in the air where it belongs. Pick up a couple ten foot Radio Shack
TV masts and a mast roof base and get the G5RV feedpoint up to 30-40
feet. Get the ends up as far as you can too. I can virtually guarantee
that you'll be amazed at the improvement in performance with your
existing antenna.

> Larrry ve3fxq

This is quite unneccesary. Use off the shelf 50 Ohm antennas and combine them with odd multiples of 1/4 wave (electrical) length 75 Ohm line. My assumption here is that htese are single band antennas and they are for the same band. Of course, the dipole will ruin the beams nice pattern.

The hamstick is about a foot shorter than a full-size 1/4 wave and twice to
3 times the money.The full size antenna covers more of the band with the
lowest SWR.Always a sacrifice when you shorten things and in this case 1'
isn't worth it.

Given the space you have top work with, I would say that your present
antenna is ok.

But your overall situation can be improved.

The best return for your dollars and your labor would be to get your
present antenna up higher. Get all of it higher......the ends AND the
middle......

The above advice might not be so true if you were already at 50
feet.......but since you say you are now at only 10 feet, raising the
antenna will show notable improvement.

hi john

i have a very small plot. 27' x 12'.....very small

what i use is as follows

66' of 450 ohms feeder from the atu.
this is the feed to the antenna up at 24' high.
off one half of the feeder i have a 25' counterpoise
off the other i have 66' of wire going over my garden and into next doors
and into some trees.
i have a great person next door :)

total length 91ft or so.
this has worked well for me and if i can hear them and no pile ups then i
can work them.
i wish i can get it higher but due to an exposed location is wise to leave
well alone.

can you get your antenna any higher because it should perform a lot better.

before spending any cash i'd play with the hight of what you have and if no
joy play with some wire.

the comercial one will work but can be built for the fraction of the cost.

hope this is of some use to you.

good luck and good DX

New HAM here- so forgive the stupidity....

a friend tells me that I can make an antenna selector to switch my 2m and 70cm J-pole's elements for my HT. Said I need to use a couple connectors, a project enclosure, and switch the center conductor between the two antennas. Join all the shields.

It seems to me that this would add an extra radiating element on the shield side of the circuit. I'll admit I'm knew to all this though, so I hope you folks can help me...

No callsign yet- tested and passed 2 weeks ago. VERY anxious!!!

Hello,
Thanks for looking at this I need some help.
I have acquired an Antenna Coupler made by Harris
it is model RF-3281. I have been told that it will tune
1.5 - 32 Mhz but I have no manual, specifications or
circuit details.
If you have any of the above details I would very much like
you to contact me :-
Mailto:G1GYC@QSL.NET

I will pay for any copying and postage.

Or can you tell me :-
1) The operating Voltage of the unit (PSU requirements)
2) The tuning range
3) The minimum wire / whip length that can be used
4) The maximum transmitter power the ATU will handle

Thanks Martin G1GYC

I tossed a similar question at this NG maybe a year and a half ago and
a lot of the gurus who hang out around here had a bunch of good
comments. Look up the thread "Do Trees Absorb RF?" per my callsign
w3rv. The conclusion was that trees have little or no effect on HF
antennas. But as the frequency goes up an effect becomes noticeable to
the extent that trees can apparently cause problems when you get as
high as two meters.

Is the 66' of feeder critical? I have room for the radiator but a sketch
shows an excess of feeder, it needs to be close to the house.

From: Roger Leone <arleone@inreach.com>
Message-ID: <3ilF7.50289$Lp2.548661295@news.inreach.com>
Source record: 155239

Although the concept is valid, in practice it is relatively difficult to maintain a 50 ohm impedance through a homemade switch. The kind of device you described will work OK below 30 MHz, but in the VHF spectrum and above, the impedance discontinuity caused by the switch will cause SWR problems.

Commercially produced switches take measures to keep the 50 ohm impedance, and some of them actually maintain a coaxial structure through the switch, but these are hard to duplicate at home.

I have found several A-B switches made for TV and VCR use that are surprizingly good at VHF. They are cheap and plentiful. The main problems with them are the F connectors and limited power handling capability. Perhaps you can find one that has connectors that can be removed and replaced with BNC's or even SO-239's. This will make a more effective switch at VHF and UHF.

As to your two week+ wait on your new call...

Depending on how fast your VEs are at getting things in, take a look at www.wm7d.net - on his call sign search page he's got a link to calls issued 'yesterday' and the like.

Found mine there 3 days after take'n my test. Yea - my VEs were on the ball!

I know there are others at least as good, but that's the one worked for me.

Do you have a need for a high-quality SMA-TO-BNC antenna adapter that is custom made to fit and protect your H.T. or scanner radio?

Adapter allows you to:
Quickly change antennas to base,mobile or different style use.
Use the more popular and wider selection available of BNC antennas.
Prevent chassis connector wear or from coming loose due to antenna changes.

Adapter features:
Gold plated contacts with a teflon insulator.
A low profile design with a rubber covering for a factory antenna look.
The rubber base seals to the top of the radio with no spacers needed for moisture and dirt protection.
The base also provides an excellent support for any length of antenna or application.
No need to remove adapter once installed to make a quick and safe antenna change.

Sizes to fit radio models:
Yaesu: VX-5, VX-1, FT-50-R, VX-10, VX-150, VX-110, VXA-100, VXA-120
Icom: IC-T8A, IC-T81A, IC-Q7A, IC-R2
Kenwood: TH-D7, TH-G71, TH-F6A
Alinco: DJ-V5
Standard: C508A, C510A
Radio Shack: HTX-200, HTX-400, HTX-245
Aor: AR-16

Previewed in the May 2000 Issue of CQ Magazine, and the Nov. 2000 Issue of QST Magazine.

$11.95 + $1.50 S+H(One to unlimited)
(Check or money order only in U.S.Funds)
(Specify radio model when ordering)

I'm glad to hear that. I recall back when the VEC program first started
that things were very cumbersome. I haven't had any relicencing issues
in many years but I sure recall the excruciatingly painful 6 weeks+
waiting for the FCC to move after passing my test. Yeah! Finally, a
'red-tape' issue has been fixed!
Its a convenient time to point out that I heard a brief news blurb that
the FCC is not taking applications by mail at this time, presumably
because of the anthrax threat. I imagine some earlier snail-mail
paperwork might be in limbo.

From: Crazy George <munschNO@attglobal.net.SPAM>
Message-ID: <3be5f6a6_2@news3.prserv.net>
Source record: 155243

Marvin:
I suspect you'll get a lot of answers on this, but here's my shot:

Balun is a word formed from the contraction of BALanced to UNbalanced transformer. It is used to match coax to open wire line, coax to a balanced antenna, or whenever the transition from a balanced system to an unbalanced system needs to be made. Originally, this function was performed by coaxial cable connected in ways described in the antenna handbooks, or by actual transformers wound on ferrite toroids. Later, the same function was implemented with so-called current baluns, which are ferrite chunks placed around the outside of the coax in selected ways to impede the flow of RF on the outside of the shield.

This latter function is the description of an isolator.

Further, an isolator is used where the antenna needs to be decoupled from the coax, even though both are unbalanced, a J pole antenna is a classic case, as is a coaxial or sleeve dipole. There it is properly called an UNUN.

It will work fine, but you might consider a patch panel made of BNC
connectors. It would be cheaper, there would be less loss, and its almost as
fast as a switch.

I have no idea really, but if it's made to match the Harris amps that they made for commercial/marine use etc, it will probably handle quite a bit. At least 500 watts anyway, maybe more. Does it look big and hefty? Like it came off a ship? They made some pretty good stuff. I know many people that have run the harris amps that they got surplus or whatever. Built like battleships by what I hear although I've never messed with them. If its ex-marine, guesswork about likely ship antennas might give you an idea on what it would do. :/ MK

I, too, am not familiar with that model number although I have used Harris gear on many merchant ships
I've served aboard. Those were the RF601A coupler and it's control unit RF601A/C. The control unit
ran from 120 VAC and included a p/s of 24-32 VDC which supplied the coupler via a multiconductor cable.
They would tune 2-30 Mc and handled a kilowatt. The control unit was rack mounted with the transmitter.
We used them with large 26 foot fiberglass whips (8 inches at the base, tapering to 2 inches at the tip).
They would probably tune a wet string. The coupler itself was approx. 30 x 18 x 8 inches and weighed about 80 lbs or so.
It was basically a rectangular box with a domed cover. The cover attached with a heavy neoprene gasket
between it and the box and the whole thing was charged with nitrogen to keep it dry.
The "guts" included a large roller inductor and a vacuum cap rated about 7 or 8 KV, both motorized.
It would tune that whip to any freq. in about 2 or 3 seconds. This may not have answered your
question given the difference in model numbers, but hopefully tells you something about what their gear is capable of.
Toronto Surplus sells these units used for 700 to 1000 dollars. Or check with Harris themselves...

I have a Kenwood 742A with a 10M module and use a hamstick with a heavy duty mag-mount. I have a 1:1 swr, very happy with the antenna.

I saw one interesting statement in the NAB paper that gives an advantage to a folded monopole.

A folded monopole will have a slightly better bandwidth (for a short one, that is).

The only way a full size whip might be bettered is with a better ground plane. For example, a shorter loaded antenna in the middle of a van's roof **might** work better than a bumper-mounted 1/4 wave of the same height. Only way to know is to try, or find somebody who already has tried.

1501. Coax switches - Worried about SWR ?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-05 14:52:39 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <9s69lh$a2s$1@plutonium.btinternet.com>
Source record: 155254

Reflections from impedance mismatches at switches in coax feedlines are often mentioned on these walls and described as something which matters. But nobody ever says how much it matters. Very often it doesn't. Home-brew coax switch makers may be interested in the following.

Inside the switch box, as the inner coaxial conductor continues through the switch wiring it is defficient of capacitance. The inside walls of the box become the outer conductor of a short, much higher impedance line. The missing capacitance is proportional to the length of bare wire inside the switch. In the worst case the missing capacitance is equal to the capacitance of the same length of coax.

Insofar as reflections are concerned the missing capacitance has exactly the same effect as an excess of capacitance of the same value. It is a straightforward matter to calculate the SWR which results from a lump of capacitance across a transmission line. Furthermore we are interested only in small SWRs and the calculation for solid polyethylene coax then simplifies to -

SWR = 1 + F * L / 1250

where F is MHz and L is length of bare wire through the switch in inches.

At 144 MHz and a bare wire length of 2 inches, SWR is approx 1.23 which might not be considered excessive. Remember it is worst-case. It could be reduced by a small fixed capacitor across the line inside the box. (1.5" length of line ?)

Reflections below 50 MHz due to coaxial switches are entirely negligible in comparison with other causes of SWR > 1:1

A more accurate worst-case formula which applies when bare wire length is less than a very unlikely 1/10th wavelength is -

SWR = (1 + x) / (1 - x)

Where x = F * L / 2500

The formula can be used in other situations (a dummy load resistor ?) where a wire replaces a short length of solid Pe coax of any normal impedance.

The term 'isolator' has a specific definition in the RF industry.

It is a device that allows RF to flow in only one direction. RF in
the other direction, such as from a mismatched load (High SWR), will
get absorbed and dissipated as heat.

They are mostly seen at microwave frequencies, say 1GHz and higher, as
they will get quite large on lower bands. I don't recall the details,
but I think it is possible to make one out of coax for the lower
frequencies.

What you describe as an isolator would, I think, be more properly
called a choke.

Goofy wrote:
"Do trees lose moisture or inner fluids during winter and if so will this change my antenna efficiency?"

The Signal Corps says on page 279 of "Electrical Communication Systems Engineering": "In dense jungles, the ground-wave range is extremely short, and sky waves must be used to a great extent in order to provide useful communication."

Terman says it can be assumed that 3.5 degrees is the minimum practical angle above the horizon at which rays can depart from the transmitting antenna (page 749, 1943 "Radio Engineers` Handbook").

Trigonometry would allow you to clear 100-ft. trees within 1/3 mile. I recall but can`t find a Signal Corps estimate of the loss trees might produce. Their estimate was 6 db but could be worse for vertical polarization than for horizontal polarization and got worse with increasing frequency.

Source record: 155257

Marvin:

As the Bard said, "what's in a name?"

"Isolater" and "balun" are two different things.

A "balun" is a device used to effect a transition in the signaling mode on a transmission system or signal path from an electrically balanced [not ground referenced] to an unbalanced [ground referenced] condition. Baluns are passive bi-directional devices which pass the desired signals easily in both directions, forward and backwards. Baluns usually take the form of a transformer of some kind, although there are forms of bifilar wound chokes that are used for the same purpose.

An "isolator" is an entirely different device. An isolator is a device which supports signal transmission in only one direction. i.e. it is unidirectional not bi-directional. It is used to isolate an input from an output. In fact, an isolator may itself be balanced or unbalanced, and a balun may be used with an isolator to effect a balanced to unbalanced transition, etc... Isolators often require some kind of active rather than pasive circuitry. A common form of isolator is simply a unidirctional amplifier.

But there are more specialized forms of "isolators", other than a simple unidirectional amplifier, which are closely related to the "circulator". In fact you can make an isolator out of a circulator and in some sense... a circulator may be thought of as being made up of three isolators and directional couplers arranged in a ring.

All that being said... it is entirely possible to describe the effect of a current balun or choke as providing common mode current "isolation".

Best,

The full size g5rv is a 102ft center fed dipole. The series section
transformer should be 1/2WL on 20m. For "450" ladder-line, that
would be approximately 31 feet, depending on velocity factor.

1512. Help matching my Yagi

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-05 17:17:35 UTC
From: "Kevin St.Laurent - AB8IU" <newsreply@durosupply.com>
Message-ID: <PQzF7.1540$IY5.1389224@newssvr28.news.prodigy.com>
Source record: 155265

I have put together a 2m yagi using a design from Quick Yagi software. All elements are using 1"diameter tubing. The array has 8 total elements. My problem is getting a good match maximizing my yagi's efficiency. I used a gamma match to transfer the power to the driven element and can't seem to get the proper combination of tubing length, diameter, and space from the driver to achieve a maximum forward gain. Using the software to determine the gamma dimensions for 146.000mhz suggested using a 5/16"diameter tube 6.5" long, spaced at 1.5". This combination gave me no better than a 1:3 SWR.

Can any one offer a matching network that would provide the best power transformation with a reasonable SWR over a good portion of the band? Or better than that, offer an explanation of what I need to consider when choosing a match for this antenna.

Thank you very much.

Most of those amps do not pass signal when not powered.

Message-ID: <3BE6D7B7.D737A489@eznec.com>
Source record: 155170

A folded antenna has a larger effective diameter, and a monopole or dipole made with larger diameter wire has greater bandwidth. The effective diameter of two parallel wires is sqrt(2da) where d is the diameter of each wire and a is the center-to-center spacing. The larger effective diameter is the reason for the increased bandwidth. You could get the same bandwidth increase by making an unfolded antenna with the same two wires just connected in parallel.

A folded monopole has a shorted stub in parallel with the feedpoint, and its reactance change with frequency is in the right direction to compensate for the fundamental antenna reactance change. Unfortunately, though, the impedance of the stub is much too high to have much of an effect. Some people mistakenly attribute the broader bandwidth to this effect.

Regarding the NAB paper -- it's always comforting when a P.E., PhD, two MSEEs, and a bunch of test equipment and research can come to the same conclusion that can be reached with high school algebra and a little fundamental reasoning. Seriously, though, it is good to see that the careful measurements confirm the fundamental reasoning. It verifies that nothing important was left out of the simple analysis.

It will probably be resonant in the 20m band. Fine-tuning the length
of the series section transformer to resonate in the center of the
20m band is the way G5RV, himself, did it.

KA3DWW wrote:
"For example a shorter loaded antenna in the middle of a van`s roof
"might" work better than a bumper-mounted 1/4 wave of the same height."

And again, it might not. I have experience with hundreds of mobile installations at 33 MHz. Most used full-length 1/4-wave whips but some used shortened base-loaded whips. All were mounted somewhere on a vehicle body. None were bumper-mounted.

The full-sized 1/4-wave whip beat the loaded whip in every case that I know of that didn`t have defects or differences in antenna height or exposure. The difference may have been small if the loaded antenna were especially good and sited in the center of the roof, but the 1/4-wave whip was better.

Best regards, Richard Harrison, KB5WZI

It's the commercial switches that I've seen with ratings like "max 1dB loss" and "max power 25W" in a small package that could not possibly dissipate the implied 5 watts loss without going into meltdown that put a smile on my face. AFAIK, they're getting that number from some juggling of (worst-case) reflection coefficient numbers, and for the most part it does not represent an actual power dissipation in the switch. As Reg suggests, if a an apparent SWR greater than 1:1 bothers you, simply compensate at the switch or elsewhere.

Cheers,
Tom

If the mismatch at the coax switch is considered to be due to the
inductance of the length of the bare wire passing through the
switch we arrive at exactly the same conclusion -

Worst-case SWR = 1 + F * L / 1250

where F is in MHz and

L is length of bare wire through the switch in inches.

Which applies to solid Pe coax of any impedance.

Sorry for this rather tangential answer, but I wanted to point out
that what you are working on is getting power to the driven element,
which is pretty well decoupled from achieving maximum forward gain.
The gain is determined mostly by the parasitic element spacings and
tunings, and not by the driven element matching or even by its length,
at least not nearly as much as with the parasitic elements. It's very
often the case that you should worry about three independent things in
setting up an antenna: configuring the elements to get the gain you
want (put the power where you want it), matching the feedline to the
antenna feedpoint to deliver power to it, and decoupling any other
conductors in the area (the feedline, for instance) so they don't
become an unwanted part of the antenna system and mess up the pattern.
You're working on the middle one of those, a very reasonable thing to
do, but it won't have much effect on the first one.

I do hope someone will have some explicit gamma match help for you...

Cheers,
Tom

Reg:
Your insights and math are always superb. I can't handle even simple equations anymore, but translating the information discussed in this thread into a table of maximum exposed length vs. frequency for a couple of VSWRs, say 1.1:1, 1.5:1, and maybe 3:1 would sure be a good shack reference.

As a practical matter, I always used coax inside the switch box to minimize the length of the impedance bump, and have made manual switches which worked satisfactorily at 2M by simply soldering the coax center conductors to the terminals of a toggle switch, and then tying the shields and switch frame together with 16 Ga. buss wire.

>

As another stated, the gain is determined by the element lengths and
spacings. The gamma match only transforms the low feed impedence of
the yagi to 50 ohms for the radio. 1.3:1 SWR sounds ok to me. Have you
tried slightly varying the point where you are attached the the driven
element? Also 1 inch elements for 2m, are kind of on the big side. I
guess no real problems, but this needs to be accounted for when
determining the element lengths if the plans used thinner tubing. I
assume you did this. If you want to get it 1:1, you will need to
experiment with the gamma lengths , attaching points , coax cap
lengths , etc.
Myself, a 1.3:1 would be fine, unless the bandwidth is real tight and
you can't hardly move around before you are 2:1 SWR. Anything under
2:1 is fine. You won't hear the difference getting it lower. MK

1533. Portable Antennas for Short Range 75 Meters

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-06 09:57:47 UTC
From: vtail@hotmail.com
Message-ID: <3be7b17f.81107934@news.netis.com>
Source record: 155189

I need a good portable antenna for short-range (<= 200 miles) SSB on 75 meters.

What is needed is a high-angle-of-radiation, so-called "cloud warmer" or NVIS type of antenna, since the low-angle types of antennas (e.g. verticals) will likely skip over the area of interest..

One choice is a 75-meter dipole strung between two trees and elevated less than 20 feet above ground.

Another is a 1/4 wavelength end-fed wire with the near end on the roof of a motorhome and the far end tied to a tree or other available support, less than 20 feet high.

The chances are that in either case, an SGC or similar automatic antenna coupler will be used to make for the best match to the coax.

This will be used for Field Day, Simulated Emergency Tests, stuff like that.

So, my question is... is the dipole likely to perform sufficiently better than the end-fed quarter wave to make it worth the extra effort to put it up and take it down?

Thanks...

> better than that, offer an explanation of what I need to consider when
> choosing a match for this antenna.

There is a bewildering array of matching systems available.
Gamma, T, Delta, hairpin and various kinds of transmission line
transformers........

IMHO, they are all horrible, complicated, fussy, nasty things.

A typical 8 element Yagi-Uda will have a feedpoint impedance
of about 15 to 20 Ohms. If you use a folded dipole as the driven
element, the feedpoint impedance will be four times greater. A
reasonable match to 50 Ohm co-ax and a perfect match to 75 Ohm
co-ax. At such high frequencies, a loop formed from a few turns
of the co-ax feeder will make a very effective choke balun.

The spacing between the driven element and the first director
is not too critical as far as gain is concerned. You can adjust
it a few inched either way until you get a good match.

Context issue. Goofy asked if stringing HF wire antennas thru trees
has a detrimental effect on the antenna itself given the seasonal
changes in the perceived "electrical" characteristics of trees. The
answer to that question seems to be that trees used to support HF
wires don't have any effect one way or another on antenna efficiency.
In a nutshell trees apparently don't shunt the RF to ground when ya
run antennas thru 'em which is his core question.

The quarter wave option will use the motorhome as the counterpoise, and while the efficiency will be a little bit lower, the real problem may be something else. If you are planning to operate in a situation where there are other electronic systems in the vicinity, as Field Day or a real emergency with other radios, computers, etc., you may experience RFI problems that a dipole further away will not be as likely to cause.

Roy, Richard:

Short vertical monopole versus folded monopole, versus thicker monopole of either variety... interesting subject. I really liked Roy's numerical illustrations. Great stuff Roy. Reg and Lord Kelvin would be proud of your posting.

Here's an interesting related practical issue...

Would a capacitive "top hat" on the monopole, or folded monopole for that matter, increase the radiation resistance without changing the ground resistance? And... could that be a way of increasing the efficiency that eludes when simply folding the element?

i.e. how much capacity hat is needed to get say a certain percentage increase in efficiency versus say laying out more radials.

Another way of thinking of this is... i.e. assume a fixed number of radials already laid out as a ground enhancement. Then pull up some of those radials and connect them on the top instead, as a top mounted capacity hat... does the efficiency increase or decrease when doing this?

Say one has a ground mounted monopole over a "so-so" ground, enhanced with say 8 x 1/5 lambda radials. What is the overall effect on efficiency of pulling up two of those 8 radials and placing them as a "T-hat" on top of the monopole, leaving only 6 radials behind.

Then pull up two more, etc.... "T" antennas and "Inverted L" are simple variations on this theme... I believe Jerry Sevick did a lot of work on this subject in his pieces on ""Short Ground Mounted Verticals", but he didn't compare efficiency gain for top versus bottom use of "radials".

IOW... what are the relative benefits of ground enhancement traded off against top hat capacitance enhancement on grounded monopoles over "ordinary" grounds. If one has the capability to do this, and can only support a finite total number of radials plus top hat wires, how should the top wires and the radial wires be distributed for maximum efficiency?

1544. Philips-Magnavox (Gemini) outdoor TV antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-06 17:25:44 UTC
From: i_dont_read_this_2000@hotmail.com
Message-ID: <2868ec5.0111060925.4ca03ee0@posting.google.com>
Source record: 155197

Any opinions on the quality of outdoor Philips-Magnavox brand TV antennas? The brand is licensed to a company called Gemini in New Jersey, although I don't know if they actually manufacture their own or re-brand someone else's products.

The models are shown in Gemini's catalog, a 1.5mb PDF file at http://www.gemini-usa.com/pdf/geminicat.pdf

Convenient sources for Winegard or Channel Master don't seem to exist around my neighborhood, but Lowes sells these Philips-Magnavox models so I'm thinking about going with the MANT-902 unless someone tells me they're no good.

One of the "features" on this brand is that the VHF/FM elements can be locked into a standard, straight-across configuration or a V-configuration. Any opinions as to which is likely to produce better reception?

Thanks in advance!

Yes. Let's suppose you feed at the base. If you add a top hat, the radiation resistance at the base increases. This reduces the current in the ground system, since for an unfolded antenna, the ground current is equal to the antenna base current. The efficiency improves. Lengthening the antenna (up to a half wavelength) also improves the efficiency. For a given resonant frequency, a longer antenna will produce a higher base radiation resistance and higher efficiency than a top loaded one. These can be easily modeled with EZNEC or a similar program.

> i.e. how much capacity hat is needed to get say a certain percentage

Ground radials interact with each other in a complex fashion, so as far as I know there's no simple and rigorous way to even fairly accurately predict ground loss resistance given the number of radials and other factors, short of something like NEC-4. (I once spent several years of spare time combing papers looking for such a method.) Reg has a program that purports to do this, but its results disagree with the one accepted set of decent measurements, the ones by Brown, Lewis, and Epstein in 1937. NEC-4 results agree with those measurements reasonably well. So I don't think you'll ever come up with even a good rule of thumb. Another problem is that because of the loss of the ground, the current in buried radials fades relatively rapidly -- certainly in a much different fashion than the current distribution on a top hat. So what might be true for one set of radials and top hat spokes wouldn't necessarily be true for ones of even moderately different lengths.

>. . .

It's an interesting question, but I believe you'd have to settle it for each particular situation. You'd need either NEC-4 or some good measuring equipment, patience, and lots of time. Or all the above.

Roy Lewallen, W7EL

The RFI is caused mostly by common mode currents. Common mode currents
tend to cause low angle radiation, an undesired effect in this case.
I would also recommend the dipole.

More radiation resistance without changing the ground resistance would result in more efficiency. Unfortunately, adding capacitance lowers radiation resistance. A capacitive hat is less lossy than a loading coil when bringing a too-short antenna into resonance. That is the hat`s contribution to efficiency.

A full 1/4-wave vertical is better than a loaded antenna.

See figure 9-65 in ON4UN`s "Low Band DXing" for an idea of how radiation resistance drops as more of an aerial wire produces capacitance in place of vertically polarized radiation.

Gary,

You will find more details if you download the HF2V manaul in pdf format
from the Bencher/Butternut web.

As owner of a HF2V , I read from the manual p 6 " With this particular
arrangement (i.e. top loading according to suggestion in the text) the 80/75
meter bandwidth between the 2:1 SWR points should be nearly 100 kHz".

There is an alternative arrangement with four 25 ft "umbrella" wires which
would provide 125 kHz of operating bandwidth. But at the sacrifice of 40 m
operation.......

I have not tried toploading (yet!).I use my HF2 V as a roof mounted GP with
band specific radials for 80 (narrow bandwidth!),40, 30, 17 and 15 meters
with good results, excellent on 40/17, using an tuner and a short coax feed.
So it can be used as a sort of multiband antenna, without traps....

Not at all. I made a gamma match for a 6m yagi about 3 months ago and
it worked right the very first time. They are actually about as easy
as you can get. No harder than trimming the ends of a dipole, etc. All
you have is a tube with a coax "cap" run though it that attaches to a
certain point on the element.

This can work, but if you spend time designing a beam with a certain
F/B and gain, messing with the element lengths or spacings can ruin
the beam. Or at least it won't work quite as designed. VHF/UHF is
critical about this. If you want a 50 ohm feedpoint, I think it should
be designed this way from scratch. If the feedpoint is low impedence
due to design, and most higher gain yagi's are, I'd rather adjust the
matching unit to give a good match rather than alter the antenna to
give a good match. The folded elements can transform the impedance,
but mechanically are not very good to deal with and I believe they
would need to be isolated from the boom.
I prefer all elements grounded to the boom. I think it's much easier
in his case to just adjust the gamma match. Thats all he needs to do.
Actually, with a 1.3:1 SWR, he really doesn't need to do anything.
It's fine as is. Just my 3 cents... MK

I have another graphical example of how radiation resistance drops with capacitive loading from ON4UN`s book. It`s Fig 9-34 in "Low-Band DXing".

Radiation resistance drops from 34 ohms to 18 ohms as the T-Top increases from 4.5 meters to 15 meters on a 3.5 MHz 1/4-wave vertical antenna.

Best regards, Richard Harrison, KB6WZI

That's true, but the fatal flaw of the gamma match is that the coax shield is connected to the boom. Since the gamma match is not perfectly symmetrical, the direct connection is a perfect way to launch unwanted current along the boom.

At 50MHz, I found a marked reduction in pickup of local computer noises etc. by changing from a gamma match to a symmetrical split dipole. The dipole was insulated from the boom and fed via a coax transformer, which was also coiled up to act as a common-mode feedline choke.

The disadvantage of this feed system is that it isn't fully adjustable - the impedance of the split dipole has to be a convenient value... but that isn't so hard to achieve (see below).

>>
>> A typical 8 element Yagi-Uda will have a feedpoint impedance
>> of about 15 to 20 Ohms.

Whoa there... that's a drastic over-generalization. You can have anything from 15 ohms to over 50, depending on how it's designed.

>>If you use a folded dipole as the driven
>> element, the feedpoint impedance will be four times greater. A
>> reasonable match to 50 Ohm co-ax and a perfect match to 75 Ohm
>> co-ax. At such high frequencies, a loop formed from a few turns
>> of the co-ax feeder will make a very effective choke balun.
>>
>> The spacing between the driven element and the first director
>> is not too critical as far as gain is concerned. You can adjust

>> it a few inched either way until you get a good match.
>
>This can work, but if you spend time designing a beam with a certain
>F/B and gain, messing with the element lengths or spacings can ruin
>the beam. Or at least it won't work quite as designed. VHF/UHF is

>be designed this way from scratch. If the feedpoint is low impedence
>due to design, and most higher gain yagi's are, I'd rather adjust the
>matching unit to give a good match rather than alter the antenna to
>give a good match. The folded elements can transform the impedance,
>but mechanically are not very good to deal with and I believe they
>would need to be isolated from the boom.

It isn't all that difficult to design yagis with the feedpoint impedance optimized to some convenient value, as well as optimizing for a good balance between gain, size and a clean pattern.

It is actually possible to design yagis for a 50 ohm feed impedance - that's at the centre of a split dipole, which steps up to 200 ohms with a folded dipole. The trick is to add an extra director quite close to the driven element, which raises the impedance without having much effect on other aspects of performance. The highly successful DL6WU series of long yagis works this way, but is also works for as few as 4 elements. As Ed says, you can adjust the match by changing the spacing of that director, or even simply bending it toward or away from the driven element.

On the other hand, you do get a bit more design freedom by letting the impedance fall below 50 ohms. The next convenient stop is 28 ohms, which can be fed from 50 ohms by a quarter-wave transformer made from two 75 ohm cables in parallel. This was the basis of the 50MHz 3-element yagi mentioned above, which was described by W4RNL in QST last year. Someone in Germany has also published some successful long yagi designs based on 28 ohms.

The lower feedpoint impedances of 15-20 ohms are falling out of favor, at least for long yagis, because they are generally associated with narrower SWR bandwidths (due to the unavoidable Q of the matching network) and also with higher internal losses due to excessive currents in a few elements.

There's a lot more information in the 'VHF/UHF Long Yagi Workshop' on my website.

1555. open wire/ladder line feed question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-07 00:24:02 UTC
From: capra <bhyuu@spiritone.com>
Message-ID: <3BE87F22.B39895CE@spiritone.com>
Source record: 155207

I'm going to put up 40 and 80 meter dipoles.

Can I feed them with open wire feedline and
get it to resonate like it will with 50 ohm coax?

How do I convert it to 50 ohms for the transceiver?

I don't want black coax hanging down and feel
open sire will be easier on the eyes from the street.

Where can this stuff be bought.

Yes, if and only if you make the open-wire feedline
exactly 1/2 wavelength or a multiple thereof. On 80m,
that's about 120 feet.

> How do I convert it to 50 ohms for the transceiver?

1:1 balun or choke.

> I don't want black coax hanging down and feel

Palomar Preamp P310 - Ebay

Covers 160 through 6 meters. I bought this at a hamfest a few years ago for $50 from a nice fellow who said that it worked perfectly. I haven't used it, so I decided to sell it. Just to make sure it worked, I plugged it in and nothing happened (rats). I opened the cabinet, and found no visible evidence of damage. (Even the fine wires to the toroids are intact, so I suspect a transistor or possibly a bad solder joint.) I don't have time to work on it. The cabinet is in excellent condition. I'm selling it strictly "as is".

I will be glad to provide additional information. Contact me at w4tq@mindspring.com

Pay by money order or PayPal. UPS shipping charges will be estimated based on the weight of the packaged item and your shipping address. I will send you the UPS tracking number, which you can track via the Internet. The item will be shipped immediately upon receipt of funds, and will be packed properly, to help assure safe delivery.

For auction on Ebay, click on:

I've bought one the 40 mtr version a few years ago. Had very little luck with it. After about 2 hrs worth of tuning the antenna I was able to make some qso's but was not impressed with the signal reports! The difference between my dipole "which was only up 20ft" and the Isotron was 59 + 10 db and maybe a 55. The Isotron was at the same height. So in short If you have no other choice then I would get it. I belive GAP just came out with some antenna like that. You might want to take a look at thiers.

another option for mobile convenience, nvis radiation, mobility, is a
centerloaded doublet, horizontal.
This allows for shorter wires, and if short enough, can only be supported in
the center.
Your distance requirements may allow for this antenna and there is software
available on the net that helps design this.
If interested just say so and I will post the url.

I am thinking about a quad and would prefer to buy rather than try to make a quality set of spiders and spreaders. Looking at the Cubex site, I see the MK-II that appears quite rugged. It is a two-element quad with 5 bands (20-10) with independent feeds, on a short boom. A 5-way coax remotely-operated coax switch can be mounted on the boom to provide a single feedline.

I can find no reviews of this antenna, or of Cubex antennas in general.

There are lots of opinions on this newsgroup. Does anyone have something good or bad to say about this antenna or company? It is not an inexpensive antenna and I wonder if the price is justified. Who else sells quality quads?

==========

Something seriously wrong. Radiation resistance of a 1/4-wave
vertical referred to the base can only increase with top C loading.

Here is the latest program (still developing), please check
http://www.verkhovyna.com/radiofest.htm
for the latest updates

****
Program for 2001 Radiofest Eastï¿½
and DX-Contestvention at Verkhovyna resort in Glen Spey, NY

Due to shortage of promotion time and concern of some contest club's members this year's program will be compressed to one day event on Saturday Nov. 10, 2001

Come, see the place, meet the people, enjoy presentations, have fun!

8:00 am Breakfast, fresh NY bagels, muffins with fixins and fresh Starbucks coffee

10:00 - 12:00 am Antenna forum

10:00 - 10:45 pm Quads, multiple polarizations and techniques by Ken "Judge" Glanzer, K7GCO
Advantages of Quads, ways of feeding, 6 polarizations, multibanding, applications for contesters.

11:00 - 11:45 pm Miracle by the ocean by Yuri Blanarovich, K3BU, VE1BY, VE3BMV
Salt water phenomena and ground effects, vertical magic, search for the most effective vertical radiator, 3/8 vertical, 4-square, quad loops, EZNEC modeling, practical results and comparisons 4 square vs. 3 el. dual polarization Quad at Cape Hatteras, NC vs. NJ

12:00 - 01:45 pm Club's Lunch meeting - official "business meetings" of participating clubs
Welcome by UACF President Steven Kapczak
Business meetings of FRC, YCCC, PVRC, MRC, NJDXA, ?....
Cold buffet lunch available

01:00 - 04:00 pm Extreme Contesting Forum

1:00 - 1:45 pm SO2R on the same band by Yuri Blanarovich, K3BU, VE1BY, VE3BMV
Problems and techniques of using two or more radios on the same band, interference, phase noise, RX overload, polarization diversity, switching system. Application is SO or MM situations. Display and demo of hardware on 10m.

2:00 - 2:45 Invited speaker (KQ2M?)

3:00 - 3:45 On the way (V26B?)

5:00 pm PIZZA BEER Party
"Banquet" speaker. Tesla RC President Yuri Blanarovich, K3BUï¿½
History of Verkhovyna resort, plans for development and activities, home to ham radio, camps, meetings, conventions, plans for building N2EE M/M Tesla RC "mother of all contest stations"

Yuri's famous gourmet Ukrainian Pizza, salad buffet and Spaten Oktoberfest Beer on tap courtesy of Tesla RC and Verkhovyna Mountainview Resort will be served. Giant hospitality suite, bar, mingle with big guns and little pistols, tell the lies, show your slides and videos and have fun as long as you can stand it.

Admission free, tax deductible donations to UACF Verkhovyna Building Fund are welcome.ï¿½
For directions, more information and latest updates please check www.Verkhovyna.com and click on RADIOFEST

See you all there!

It can fry tree branches if the wire hits the tree towards the end of
the wire.:) A KW usually needed for advanced tree burning effects.
Green branches seem to work best as they seem to be the most moist. I
fried a few pretty good one time when I was using uninsulated wire and
1300w. I've since changed to insulated with no problems until it wears
away...I never noticed a thing with the SWR..But I once dropped an
antenna leg on a guy wire and it was arcing like crazy and I didn't
notice it either until someone knocked on the door and said I had a
fire on the roof. "advanced arc/spark effects" My henry never
flinched. I was kind of surprised. I would think I would have noticed
something. I see grid and plate current at the same time on the
meters. It seemed normal the whole time. MK

I have used one since 1998. It is at 84 feet above a Force 12
EF-240/420. It does a decent job giving all 4 bands, 17-15-12-10.
Sometimes I wish I had a little more gain on 15 and 10, but then it is
far superior to what many others have on 17 and 12.

It also works reasonably well at lower heights. I have used it as low
as 35 feet when some DX suddenly came along and the tower was cranked
down.

I expect to be moving next year, and will take these antennas with me.
I guess that is an endorsement.

Reg wrote:
"Something seriously wrong. Radiation resistance of a 1/4-wave vertical referred to the base can only increase with top C loading."

My first reaction too.

John Devoldere, ON4UN wrote:
"To bring a short vertical to 1/4-wave resonance, the total T-wire length should be about twice the length of the missing portion of the vertical mast. Fig 9-33 shows a typical configuration of a T-antenna. Two existing supports, such as trees, are used to hold the flattop wire. Try to keep the vertical wire as far as possible away from the supports, as power will inevitably be lost in the supports if close coupling exists.

Fig 9-34 shows a design table that was derived using the ELNEC modeling program."

Fig 9-34 is a figure-X that is made by straight lines having opposite slopes. The radiation resistance ascends as te vertical gets longer and requires less flattop for resonance while the horizontal wire length on the graph descends.

In the Fig 9-34 example, the feedpoint resistance is 23 ohms with its flattop. This is a reduction from the 36.6 ohms John`s equation 9-7 would produce were the length 90 degrees (no top loading). My take on the flattop example was that a 1/4-wave open-circuit antenna`s high tip impedance would be transformed to something lower at the base and that tip capacitance would be converted into inductance.

But, who am I to argue with ELNEC and an ARRL publication. Everything is surely checked, rechecked, then checked again.

Best regards, Richard Harrison, KB5WZI

Good morning, Keith.

Actually, the higher you get it, all else being equal, the lower your
angle of radiation. This is exactly what you don't want for
short-range communication.

I seem to recall reading somewhere that an effective NVIS antenna
shouldn't be more than about 1/8 wavelength high, which at 75 meters
is a bit under 30 feet.

Source record: 155080

Hi

I have a 50 ohm unbalanced broadband (1GHz - 2GHz) antenna
which I want to connect to a 75 omh unbalanced tuner input.
Any idea about a 50 to 75 ohm transformer for this band?

Sam

> But, who am I
==========
You are Richard Harrison, KB5WZI
==========
>to argue with ELNEC and an ARRL publication ?
==========
and you have a perfect right to argue with whatever Authority you have a disagreement.

An unloaded 1/4-wave vertical has a very non-uniform current distribution. It is sinusoidal. Current is a maximum at the base and zero at the top. The base feedpoint impedance is a purely resistive 37 ohms.

Top loading shifts the point of current maximum upwards. Although still sinusoidal the current is more uniform. There is current at both top and bottom and radiation resistance MUST increase. Furthermore, the antenna behaves as 1/4-wave impedance transformer which also has the effect of increasing feedpoint resistance. Zin now has an inductive reactance component and needs a series capacitor to tune it out.

But why anyone would deliberately top-load a 1/4-wave vertical is a mystery to me. It would have a negligible effect on both efficuency and radiation pattern. The situation could arise when a high 10m centre-fed dipole is converted to a T-antenna on a much lower frequency at which the feeder length is 1/4-wavelength.

Maybe it's just because the groundplane is (presumably) outside versus the pullout antenna on the scanner? Either you are picking up some sort of electrical noise on the groundplane or maybe as you suspected, a bad electrical connection in the coax/connector area at one end of the coax or the other. Physically inspect the entire length of coax for cracks in the jacket and check the connectors for proper installation. I thing you might try is to put a 50 ohm dummy load in place of the antenna and see if you still get the noise and if so, is it as loud as when connected to the ground plane antenna? If it's still there and just as loud, it probably is a bad connection or bad coax...fix or replace. If the noise is still there but considerably weaker, it's probably that you are receiving some transmission of noise from afar...maybe a bad insulator on the power company lines, etc. You might even be picking up some RFI from something in your home near the ground plane antenna. Try relocating it if possible and see what happens.

Yes Ian. I think I have confused an antenna which is exactly
1/4-wave in height with a shorter antenna which has been top-loaded
to behave as if it was 1/4-wave resonant.

But whichever it may be, *for a given height*, adding
top-capacitance loading always increases radiation resistance
referred to the base. I doubt if ELNEC is wrong. If there *is* a
fault it probably lies with whoever inserted the model and
interpretted the results. And the ARRL publication probably
plagiarised the story without checking its validity. Just
uessing - I don't have ELNEC nor have I read the article in
question.

Sam may be able to use a tapered line to match a 50-ohm antenna to a 75-ohm receiver over a very wide frequency range. Tapered lines are used as a single wire over a ground plane (half the impedance of a parallel line) as well as in the balanced line variety.

See the example on page 19-25 of the 19th edition of the ARRL Antenna Book where a tapered line is used to step up the impedance of helicals to parallel down to an impedance of 50 ohms (a No.12 wire at 0.57 in. over a ground plane is 200 ohms and 4 wires in parallel are 50 ohms). There is a Fig 19 on page 24-15 of the Antenna Book which gives spacings versus Zo for parallel lines.

My guess is that if you were to take about a foot of 3/8-in. tubing and shift its spacing to the plane from a quarter inch to an eighth inch, you might come close enough to shifting Zo from 75 ohms to 50 ohms.

Best regards, Richard Harrison, KB5WZI

The GEM quad is an exellent antenna and has been around for years. Had
one back in the late 70's, a 2 element. Worked great, then a lightning
strike, I took it down, only repair was getting some enamled wire from
an electric motor repair shop. However, due to family and work I lost
interest in ham radio and sold it before going back up with it.
My friend and elmer has had one since the 70's, before me, and is still
using it to this day, and still loves it.
The only thing back then was the thin plastic spreaders for the tuning
stubs. They were really prone to melting when soldering the wire around
them. I used one as a pattern and cut new ones from scrap plexiglass.
They my have redone those by now.

Reg wrote:
"But why anyone would deliberately top-load a 1/4-wave vertical is a mystery to me."

Well, frugal broadcasters use top-loading to lift the tower`s current loop (maximum current point) above the earth`s surface. This increases radiation along the earth`s surface which broadcasters prize. Broadcasters use top-loading where taller towers are for some reason impractical.

Top-loaded mobile radio antennas seem to score well in amateur shoot-out contests too. The h-f mobile antenna must be too short because of its environment, and capacitance is usually more efficient in resonating the antenna than is inductance.

As reg implies, you don`t need a top-hat for resonance if you have a 1/4-wave vertical.

Best regards, Richard Harrison, KB5WZI

I think there is some confusion here. The book is talking about a shorter than
1/4 wave antenna brought to resonance with top loading.

The chart in question (figure 9-53 in the 3rd edition) clearly shows the Rr
increasing with vertical height, with the length of the top loading wire
decreasing ~ proportionally.

That is a persuasive argument! Take current away from the base to supply higher regions in the antenna, and Ohm says the voltage to current ratio rises.

I decided to go with the 2 element Gem quad because of its boomless design, optimal spacing on each band, and ability to cover all bands from 2 meters to 20 meters. Bought mine a year ago, and they're still using cheap plastic spreaders for the stubs and coax-to-loop connections. I also re-designed mine first chance I got.

I feed my HF loops with three pieces of coax, and combined 10+12, 15+17, and 20 by itself. I chose this arrangement because that's the same frequency spread used by my Icom amplifier and antenna tuner - making bandswitching a snap.

Other than that, I love the antenna, and it works great for me.

hi to everyone who helped with the question.

i've built a full size g5rv fed with 450ohm feeder....one or two issues
though

i tunes ok on the lower part of 80m but not on the higher part. played with
adding more coax and this has helped and now tunes all the 80m band

tunes up on all band no probs.....

i have not tested the tx yet but rx has a few more s points but this could
be conditions and will have to check over a period of time.

the test will be on the usual net on 80m with people i work regulary.

will post the results.

thanks once again for everyones help.

regards

That clarifies the situation. The radiation resistance drops as the T-Top length increases because there is a corresponding reduction in length of the vertical wire.

The vertical wire length is more effective in producing radiation resistance than is the horizontal wire length.

"Unfortuntely, adding capacitance lowers radiation resistance."

That was wrong, unless one adds "as compared with lengthening the antenna to reach resonance". I did not, as I had misread data. Wes, pointed out my mistake and I appreciate the correction. I apologize for a misleading posting.

Best regards, Richard Harrison, KB5WZI

A perfect match on 20m does NOT equal a perfect match on any of the
other bands. With the possible exception of 20m, the G5RV requires
an antenna tuner on almost all other bands.

If I remember right, gold is a better conductor than silver or copper.
If you decide to build your beam out of gold, please give me your
address. :-)

1600. Re: HF Mobile Amps??

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-07 19:06:09 UTC
From: Gary - KJ6Q <davison7@gte.net>
Message-ID: <BCfG7.858$up3.132724@dfiatx1-snr1.gtei.net>
Source record: 155105
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.misc

I installed the Ameritron ALS-500 500 watt solid state amp in my truck a lttle over a week ago -
getting absolutely GREAT signal increase reports on all bands I currently use - mostly 40 and 20
meters. I used Hamstick monobanders successfully - tho the coils heated noticeably at the higher
power, so I removed the coil wires from a 15 meter stick and installed an AirDux coil about 5 inches
long and 2 inches in diameter - I adjust it for the band I want with an alligator clip - works as
well as the stock sticks, no heating, and one antenna works from 40 to 15 meters...

From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <9sc2upggg1@plutonium.btinternet.com>
Source record: 155108

Simple pre-selector consists of parallel tuned circuit with random wire antenna and receiver tapped down coil.

Enter diameter and length of coil former (toilet roll tube?), tuning capacitor maximum pF, mid-band frequency, antenna length, receiver input resistance.

Program will tell you wire gauge, number of coil turns and where to tap things into. Also 20 dB bandwidth.

Download in a few seconds from website below.

True but 20 Ohms is fairly typical for a gain optimised Yagi.
The folded dipole still seems like a good choice to me.

I must admit, it's a long time since I made a 2M Yagi. The
last one had a wooden boom and a folded driven element and
performed very well.

1605. Mast mounting a Vertically Polarzied 2M Beam

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-07 19:35:54 UTC
From: jxs2151@mindspring.com
Message-ID: <9sc2ermkr1@slb6.atl.mindspring.net>
Source record: 155106

I am mast-mounting a 2M 4 element beam vertically to a metal mast. My question is whether the mast should extend the full the length behind the reflector element or if it is okay for the mast to extend only half-way up .

My concern is that if the mast acts as a reflective element and is only half the length of the reflective element of the beam, it will skew the pattern in the vertical plane.

> short-range communication.

True, but on 75 m, you have to get way high for this effect to hurt
you working regional on that band. You will likely have a stronger
close in signal with the antenna at 40 ft, than you will with it at 20
ft. Why? The ground losses are less. In order to hurt close in work ,
it would have to be waaaaaaayyyyy high.
40 ft is still low in WL on 80m.
>
> I seem to recall reading somewhere that an effective NVIS antenna

In theory maybe, but I don't agree with that in the real world. You
have to consider other factors, like ground losses. I've never been
able to notice a drastic difference in the skip zone going from a low
80 dipole to a medium height one. In most all cases, I would have the
better signal to 95% of the people on the higher antenna. MK

I think the answer to that is to use a delta,T, or whatever "dual"
symetrical gamma match.

I've heard about that from others, but I guess I lived a charmed life.
At this time , I've got two yagi's up that use simple unbalanced gamma
matches. "ones a 3 el for 2m, and the other is a 3 el for 6m." Both
are among my quietest antennas as far as shack noise pickup. And
neither have a wound coax choke below the feed. I guess I just got
lucky...
>

> It isn't all that difficult to design yagis with the feedpoint impedance

> balance between gain, size and a clean pattern.

Not at all. I've got a load of them I've modeled. Some use an appx 50 ohm feed, some don't. If I shoot for max gain, it will usually be a lower Z feed though.

> On the other hand, you do get a bit more design freedom by letting the

I've never tried that method...Should work fine though.

> network) and also with higher internal losses due to excessive currents
> in a few elements.

Both of mine use pretty low Z feeds. My 6m 3 el is a standard NBS yagi. It's feed is 12-13 ohms or so. So is the 2m version. But these antennas are set up for maximum gain with a medeocre F/B ratio. On the other hand, my HF yagi "A4S" is designed to have a 50 ohm feedpoint. All you add to it is a 1:1 coax choke. From what I've seen modeling yagi's , you can easily set them up to get a 50 ohm feed, but they will almost always be a compromise as far as gain. But many times the f/b can be very good. They rate my A4 as 8.9 dbd??? gain with a 25 db f/b ratio. That f/b is pretty good for 3 el. The A4S is a physical 4 el, but only 3 el working on any one band. They do that to get a better element spacing on 10m as 10 has it's own reflector. Almost any time you set up for max gain, expect a pretty low Z feed. Myself, I like both versions depending on what I want to do. I like the 50 ohm feed on the hf beam, because it makes things simple for a multiband beam. On my single band, single freq beams, I go for max gain usually. On 2 and 6m, I don't need a good f/b like I do on HF. MK

Silver is best. Gold way behind, but it doesn't tarnish.

> Also, I've heard and read a little on ionic fluid antennas, but
> does anybody know of relative conductivity of various *fluids* ??

Pure water is a non-conductor, conductivity depends on dissolved salts,
oxides (eg acids), hydrides (eg alkalis)

I can't think off-hand of any pure liquids that conduct (except mercury ;)

Just checked out their site. Whoa!!!! Prices sure have exculalted since
1978. If I remember correctly, the price I paid was less than $150 new.
Darn, nothing's changed in the design or manufacturing, but price has
more than doubled.

Also, if you do get one, they say use nylon tie wraps to attach the
spreaders to the short braces. These are what hold the tension and
shape. You should also drill the very end of the braces past the
spreaders and place atainless steel cotter pins to keep the spreaders
from slipping off of the brace ends over time flexing in the wind.

1610. Short G5RV Installation Idea

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-07 21:16:43 UTC
From: Lew <lewis-jean@mediaone.net>
Message-ID: <%whG7.914$x_2.255882@typhoon.jacksonville.mediaone.net>
Source record: 155114

Since I rent and do not have much room for a antenna,
I think I have come up with a way to use the Short G5RV

(1) Mount it in a V
(2) Each leg is 20.5 ft long top end 18ft in the air
(3) The top of each leg 35ft apart
(4) The bottom 4 ft of the V is flat 8ft and above ground
(5) Feed with 14.4ft of vertical 300 ohm twin
(6) The 300 ohm twin lead connects to 52ohm Coaxil cable feed (50 ft long)
to a MFJ -941 tunner

The above will make each side of center 20.5ft long with a 14.4ft tunning
stub.

I would like some comments on the above

Please email comments since AT&T is having trouble with the newsagroups

1611. Re: Anyone have a GemQuad?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-07 21:20:48 UTC
From: Jeff Pierce <piercejhsd009@earthlink.net>
Message-ID: <3BE9A5C5.91B136B4@earthlink.net>
Source record: 155113

I had one years ago. A real good performing antenna for a 2 element beam. The main reason for the "boomless design" is that the angles of the spreaders allows each band's elements to have optimum spacing and loop circumference. Unlike a tri-band yagi that uses traps on the elements for length and then uses the "best fit' for element spacing. Meaning none of the operating bands is optimally spaced.

If you want a quad, they are the way to go. Look at some other sources for the pros and cons of quads I believe that biggest advantage is receiving with that big wire loop.

They have always been a mom & pop operation, but they have been around for over 25 years, I bought mine in 1978.

If the back element is really a reflector it should not mater. If the
back elemnet is the driven element like some beams have then you need to
extend the mast past the top of the beam by several inches or more.

1613. Re: Portable Antennas for Short Range 75 Meters

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-07 22:11:32 UTC
From: Ralph Mowery <rmowery@dialpoint.net>
Message-ID: <3BE9B194.7E52725B@dialpoint.net>
Source record: 155116

The antenna can always be put up around 30 to 40 feet and a wire put
under it about 6 to 10 feet off the ground and a few feet longer. The
spacing can probably be adjusted for a match that is close to 50 ohms.
This makes a 2 element beam with the signal going up to be reflected
back down for short range work. If longer paths are needed you go to
the middle of the lower wire and open the middle of it.

1614. Re: Quad

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-07 22:25:04 UTC
From: Bill Ogden <ogden@us.ibm.com>
Message-ID: <3BE9B4C0.1A375298@us.ibm.com>
Source record: 155117

I thank everyone for their help with my initial quad question. I usually read QST (only) and it must have become too expensive for quad advertising. The www.eham.net site is great.

The web sites of the various quad menufacturers mentioned thus far are rather sparse when it comes to details. In particular, details about feeding the things. We seem to have choices of individual feeds for each band or a transformer providing a single feed for all bands. I suspect that these two choices require different tuning arrangements, and probably produce slightly different performance results.

It seems to me that, for a given feeding arrangement, it should be possible to assemble it according to directions and have it just about right. Some of the eham comments imply that considerable tuning was needed with some units.

I was hoping for descriptions of the installation options, with comments about tuning and performance, and maybe some bandwidth (SWR) curves. I want to avoid too many trips up a tower!

Judging solely from the Web information, the LightningBolt sounds like the best starting place. I asked a few questions (e-mail) and will see how the vendors reply. They all sound like small operations, but I have no problem with this if they have been around a while.

Gold seems to be third on the list of conductors, behind silver then copper. Also you have to assume the temperature is normal room temperature as some materials seem to loose almost all resistance near absolute zero or a few deg above that. Maybe as much as 100 deg above with some special materials. Not sure how much but carbon looses a lot of resistance if it is heated to a very hot temperature.

1616. 160M antenna ideas?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-07 22:30:23 UTC
From: Sideband <sideband@spam.me.not>
Message-ID: <3BE9B5A3.5B80510A@spam.me.not>
Source record: 155119

Greetings, Gents...

It's been awhile since I posted a question of this magnitude, but I'm at a loss...

I'd like to use 160M from the apartment (yes, Apartment), but the G5RV isn't all that efficient on that band.. The MFJ-941D I'm using for a tuner does tune in a decent SWR, but the receive and transmit are lacking.

What ideas can you gents come up with for a small in size, yet efficient antenna for 160M? I have a couple trees nearby that I'm using to hold up the G5RV. What I'd like is something that can be hidden nearly as easily as the G5RV, is easily constructed out of available components (I have about 1/4 mile of aluminum electric fence wire on a spool handy), and that will be efficient enough for that band...

Thanks in advance for your input.

Careful, careful... The last time that someone stole an antenna (or was it just the reflector ?), it almost caused an intergalactic incident.

I had one many years ago (mid-late 70s). Even then it was a mom and pop outfit up in Canada.
Boomless construction allows you to get the ideal spacing on each band...plus you don't have the weight of the boom. IIRC, the bandwidth was quite wide...wide enough to where I don't remember it as an issue (as with yagis).
I liked the antenna very much and it was very sturdy...at least for my weather conditions.
The weak points were that they used simple ty-wraps to attach the elements that didn't hold up well. That would be easy to improve on if they haven't done so already.
I've always favored quads over yagis but they are a bit more trouble to get mounted on a guyed tower.
Good luck,
Bill WX4A

Might be some off-frequency interference where the Rx and the scanner have different IFs and so forth. Is the "noise" only on one particular frequency (seems so since you wrote "same freq") ? If you can get the specs for your Rx and do some math, you might be able to track down the true frequency of the "noise".

Furthermore, the slightly higher conductivity of silver relative
to copper makes it not worth the trouble and expense of silver
plating copper wire, etc, just to reduce HF skin resistance. It
just looks nicer for a short while.

Okay now,

Time for some response I think.
First, I see I should've specified a temp. range --Bad Boo-Boo on my part.
"Temperate", Room temperature, that sort of thing. I never meant to
imply including semiconductors at zero + 1 deg. K. <grin> My goal here
was mostly just to find out if there wasn't an uncommonly used metal that
might be expensive or not easily mass-produced, but was a superior
conductor. One person e-mailed that Selenium was actually number one.
Given that it's deadly poison I'll pass that one by.

Second, it was also wrong of me to post "fluids" when I meant to include
fluids with dissolved salts; i.e., saltwater for instance. I didn't know that
H2O was a non-conductor. Leads to a funny question: If I'm electrocuted
in the shower, are you saying it's the soap-scum that killed me and not
the water ? (current thru same that is).

Sure would look purty...I did make my latest 6m yagi out of solid
copper tubing. All one piece, 1/2 copper elements brazed to the 1 inch
copper boom. It's already starting to look pretty dull...:(.
Fortunatly, the corrosion doesn't hurt the rf properties much. It
should turn green after a while. Natural camo... I oughta sand it down
and paint it with some kind of sealer I guess. MK

Either way should work ok. The decoupling from the mast is very good.
This is kind of related to the past threads of dual reflectors and
their merits. There might be a slight skew, but I wouldn't think it
would amount to much. Feedline radiation would likely cause more
problems. "skewing the pattern up off the horizon or off center from
where it's aimed. MK

That could come in handy. I've been thinking about a preselector or
filter to cut AM-BC crud on the longwave band. "mainly for the
ic-706". I have a circuit for a low pass filter I'm going to try. I
might try a preselector also. MK

Paul, download program VARNEY from website below. It's exactly what you need for pruning antennas and feedline lengths to suit your own hamband requirements.

Compare performance of any type of dipole feedline arrangement with any other type and take your pick.

Thanks Ray for taking the time to respond. For the setup I am looking
at here I would place the antenna probably on a 60' tower. It looks
like this antenna is equivalent to a 3 el. yagi on each band.

Best regards, good luck in your move.

Palomar High Power 4:1 Antenna Balun - Ebay

High Power 4:1 Balun. This is the Model SB-4, which was made by Palomar. This is a heavy duty model, designed to run 2000 watts continuous power, at SWR's up to 10:1 (Palomar's specs). The impedance ratio is 4:1. Great for high-powered long-wires or loops. I was using it with a 202' long-wire, and had excellent results on 160 through 15 (using an SB-220).

Condition is "like-new". I paid $75 for this about 5 years ago (I took down the long-wire three years ago). When I was using the balun, it was mounted indoors, so it was not exposed to the weather.

I will be glad to provide additional information. Contact me at w4tq@mindspring.com

Pay by money order or PayPal. UPS shipping charges will be estimated based on the weight of the packaged item and your shipping address. I will send you the UPS tracking number, which you can track via the Internet. The item will be shipped immediately upon receipt of funds, and will be packed properly, to help assure safe delivery.

> What are the disadvantages of not having a boom like other
> quads?

No big advantage,some say the angled spreaders make for optimal element spacing but if you measure the thing you will see it is far from optimal.The Lightning bolt has a boom but achieves different band spacing by bowing the spreaders with the wire tension.Besides the spacing on a quad is not at all critical.
>
> What a the real bandwidth of this antenna?

Any quad should be fantastic,my Lightning bolt far exedes the amateur band edges!

You can tell I like Lightning bolt ,they are well built,work great and the 2 element 5 band is about $300!TG

Bill. I had a 2 el Cubex Quad in the '70s and early '80s on a 37 ft Triex crankup tower. I loved it. I worked 290+ countries with it. It's final downfall was a BAD hurricane that hit Houston in 1983. Even then I only lost a couple of the spreaders. The spreaders were one piece fiberglass. Mine was only 3 bands 10/15/20. At that time Cubex was in California if I'm not mistaken. As far as quads go I don't think you can go wrong with a Cubex.

Good luck.

Source record: 155144

Gem Quad is very nice antenna. Excellent performance especially if you take the time to tune each of the reflectors for minimum sig off the back, at the point in the band that you usually operate. Most people never make this effort with quads but it is well worth the time spent especially if U like to reject adjacent signals that are coming in from the back.

If U get one, before assembly, immediately spray paint the fiberglass arms with a couple of coats of Blue Rustoleum enamel paint. This will seal the tiny loose glass fibers that will go right into your skin when handling and will make the arms less susceptible to UV damage. My friend did this. His is up about 8 years and the arms look virtually brand new!

Also, try feeding it with balanced line and split the 10 and 15 feeds from the other bands. Feeding this antenna with just one feedline on all of the D.E.s sometimes creates F/B pattern distortion on 10 M. Use of balanced line and a tuner will allow you to operate on bands that you don't have an actual driven element or reflector for. Poor gain and F/B but it will allow U to get a signal out in a pinch.

Use either 450 ohm or parallel runs of coax as your balanced line.

The child runnning around is probably itchy from handling all the fiberglass! Hi.

1643. Elev GP misinformation?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-08 02:57:39 UTC
From: Jay Kolinsky <jkolin@worldnet.att.net>
Message-ID: <DwmG7.102647$WW.5973990@bgtnsc05-news.ops.worldnet.att.net>
Source record: 155145

About 7 years ago QST published an article by Al Christman concerning extensive computer modeling of elevated GPs with 4 elevated radials vs ground mounted verticals with 120 radials.

As I remember, Al claimed that an 80M elevated GP with the base about 15' above ground would equal the performance of a ground mounted vert with 120 radials.

Recently I've seen some posts in newsgroups claiming that for an elevated GP w/4 radials to equal the performance of a ground mounted 120 radial affair, the base of the GP would have to be at least 1/4 wave (65 ft) above ground!

Has Al Christman's work since been proved incorrect?

============================
Hello Mark.

You'll need about 250 feet of 36 gauge wire on a toilet roll tube to resonate on mid-band = 200 KHz Once you start winding you dare not stop in case it all springs off again. Make arrangements to anchor both ends of the winding before you start. Best to have a mandrel of some sort rather than hold the former (with taps sticking out) in one hand while winding with the other. Unless you can think of some way of tapping the coil after it has been neatly wound.

Regards, Reg, G4FGQ

I suppose that a guy could wax it up somehow but the general concept
that the skin effect of copper tubing will be affected because it turns
brown like a penny is a non-event. Real oxidation would be a different
story but copper really doesn't get nasty without severe outside
interference...otherwise you'd be well advised to trash your whole radio
before worrying about a copper tubing antenna degrading.
For the weak at heart, I guess you could varnish the whole thing with
polyurethane but then somebody would question how that affects the RF.

Sure. Plain old clear acrylic spray paint (Krylon) does the job nicely. As for skin-effect, I do ot know, though I assume paint causes some very small decrease in velocity.

I don't know, but I sure don't agree with it. Neither do writings made
before that time either. And I also did the same modeling exercise
here. The modeling I did came very close to agreeing with the 4
radials at 1/2 wave up = 120 on the ground statement. I have a graph
in a Bill Orr antenna handbook that covers this also. And the modeling
I did agreed with his graph pretty close. I came to the conclusion
after all of that , that the graph was fairly correct. At 1/2 wl up -4
radials needed, at 1/4 wl up -8 to 10 radials needed, and at 1/8 wl
-appx 60 radials needed. 1/8 wl is appx 32 ft on 80m. So at 32 ft, you
would need appx 60 radials to equal 120 on the ground. 32 ft!!!, not
15 ft. At 15 ft, heck, you probably need 90. This was also verified by
a reader of this NG when he compared an elevated 80m vertical at 10-15
ft with 4 radials to the same antenna ground mounted with 60. The
elevated antenna was a dud. The ground mount worked well. Anyone
expecting a 80 vertical at 15 ft to work well with only 4 radials is
in for a rude surprise. The ground losses will eat your lunch over
most average soils. It will work better than a ground mount with 4
radials though. People ignore this and wonder why their verticals
don't seem to work. There is no free lunch. :/ MK

I don't worry about it rf wise. When you consider that many people
leave a thin 14 gauge wire outside for 15 years without giving it much
thought, worrying about a fat 1/2 inch copper tube would be silly.
Also I think I remember someone saying that the corrosion from copper
is a fairly good conductor compared to other metals. It was bright and
shiny when it was new about 3-4 months or so ago. Now it's a dull
brown. Later it should start to turn green. It works great. It's the 3
el 6m NBS yagi that is in eznec. And in receive tests on a local
contester the gain and f/b almost exactly matched the model. I used
the same exact 1/2 inch element widths as the model. MK

1657. Re: HexBeam v. GemQuad Which is better?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-08 13:14:44 UTC

Source record: 155160

It all depends on what "better" means to you. The HexBeam (assuming you're talking about the 5 band model) is physically smaller, much lighter, has less wind resistance, takes less torque to turn (a heavy duty TV rotor is more than adequate), displays less than 1.5:1 SWR across the entirety of the 5 bands it covers, requires no tuning at installation time, has an inherently more durable physical structure.

Based on my experiences with both Hexbeam and 2 element quad (not a Gem quad), the quad offered much better front/back ratio in the portion of the band it was tuned for, less SWR bandwidth, a sharper forward lobe, perhaps more forward gain, shorter time between repairs, fairly simple reflector tuning via stubs. In my quads, the movement of the elements and support arms in high winds often resulted in broken element wires. If you're constructing your own antenna, you'll likely find it much easier to get the quad working properly, since there's a large body of information regarding element lengths, tuning, matching. A hexbeam for five bands would be quite a challenge, as not all of the element sets are resonant where you'd think they should be (at least in the commercial version). A properly done hexbeam can use a single feedline for the five elements with no feedline switching or matching mechanisms.

The LightningBolt web-site is pretty crappy but the antennas
perform very well. I know several satisfied customers and I
have read some very favourable reports about their after-sales
service.

Don't be too impressed by manufacturers claims. 7dBd (9.15dBi)
sounds a bit optimistic for a two element quad.

When we used to build 1/48th scale brass models for HF shipboard antenna model studies, we would spray the entire ship with Krylon so that it would keep its luster. No matter how important the RF work was, everybody wanted the model ship to look nice for display later on. The Krylon never affected our measurements. We generally did not spray the antennas because we worked with them so much. However, at HF, the entire ship's super-structure became part of the antenna.

Did you see my post about quads just yesterday? I have a Gem Quad and like it for the optimal spacing, the ability to feed each band separately, and the multi-band geometry (it will hold loops for 2 meters through 20 meters).

I have designed an Excel spreadsheet that graphs the SWR curves of any antenna over the operating portions of the HF bands, and have plugged in all the SWR readings for 10 - 20 for the Gem Quad. I use this to compare the actual bandwidth to the "advertised specs", as a reference when operating near the band edges (do I need my tuner...?), for tracking any changes as I tune the antenna, and for monitoring trends in SWR shifts as the antenna ages.

If you are interested, I'll ship you a copy as an email attachment. Let me know if you want the spreadsheet itself (you'd need Excel to open it and make changes), or just a PDF printout of the curves for the Gem Quad.

My understanding is that the Hex doesn't have as much forward gain as
a two-element quad but the f/b is quite good and it takes up a whole
lot less space. The choice depends on your specific operating and
installation circumstances.

1664. Hearing the weak ones on the low bands

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-08 14:26:03 UTC
From: Harry Williams <harry.w.williams@syntegra.com>
Message-ID: <3BEA95FB.9635E6@syntegra.com>
Source record: 155166

Well my last post had to do with bleeding off static from my full sized 80 meter vertical. I had a
lot of ideas on how to accomplish that and will probably end up either using a 1mh coil to ground
or one idea was just simply put a 1 meg resistor to ground. Thanks to everyone that responded.

Since that time I have got my vertical up. Its 60 + feet with 60 radials. SWR across 80 is great and it seems to work just fine. Now the problem. I hear stations down on the lower end
of 80 working dx, like JA's, and these stateside stations are giving the JA's reports of 569 to 589
and I can barely hear them (the JA's). My noise level is low, s1 on the meter, but neither my vertical or my full
size loop can dig these guys out. So how can a stateside station that is 300 miles away from me
here these JA's at say 58 and I can barely detect they are there with either antenna? Can propagation
be that selective on 80 meters or would something like a beverage antenna on receive make that
dramatic of a difference. Someone enlighten me....please....

Thanks,
Harry - w0piy

Brent, my set up is this, I run and ICOM 706 MKII and feed a Ten Tec Hercules solid state amp (550W). My antenna is a Bandhopper screwdriver. This is installed in an '87 Camry. The amp and 706 are trunk mounted and I have the control heads up front. The TenTec makes a remote control head for the Herc. I also added a second battery also trunk mounted.

Have had great signal reports and its a ball to operate from the car.

> In antennas, there ain't no such thing as a free lunch.

It all depends on what you expect from the antenna itself. The "ISO" Sotron Bilal antennas were not designed for DX purposes. They were designed for NVIS work in a military application. Most routine and combat radio traffic is made within a 20-50 mile or so range. These antennas perform beautifully in this particular application. The fact that these antennas are portable make them an excellent choice when working in the longer wavelengths in a NVIS situation. You also have to keep in mind that military radio traffic is rarely 59 to begin with due to the variety of station setups that may be attempting to communicate with each other.

Uhh, you should tune it on the ground. If you do so, there's no reason to have to tune it again once its mounted.
The normal config is to use a tuning stub and you'll find it very non-critical. If its on a tower you'll be able to reach it if you want to.

Insert a small variable capacitance network on the driven element. For assembly instructions pick up the book "All About Cubical Quads" written by my god, Bill Orr, W6SAI. All total the completed matching device should cost you about $4.00, and when sealed properly should outlive us all.

Working JAs on 80 is typically 'grey-line' dx-ing and yes, an hour of
time difference can make all the difference in propagation.
And remember a "589" sent to a JA on 80 is alot different from a 589
sent to the guy in the next state over.

Yup, I've built one. I still have it in case I ever need to put up a decent 2M antenna in a hurry. My was built straight from the ARRL Handbook, and it could hit literally dozens of repeaters full-quieting. I took it down when I built an 8-el beam to replace it.

Good points, Mark

People tend to forget that all those elevated radials collectively carry the same current as is fed to the actual antenna element. Thus, they can radiate. Not much if perfectly symmetrical, etc. but any radiation results in ground loss and the closer the radials are to the ground, the more the loss.

The first vertical I put up a long time ago, I put up on a 35 ft mast and used the guys as radials. Very poor performance.

Since then, I ground mount and use all the radials I can stand to install.

I can attest to this point myself. I have a ladder line-fed dipole up about
30-40 feet, cut for 80M and tuned with an antenna tuner. I have *never*
heard a DX signal on that antenna in my (admittedly meager) 4 years on HF.
All I ever hear is US stations aplenty, even at optimal greyline times.
I stopped even bothering long ago. I hear enough DX on 10, 15 and 20.

Most are incomplete and just copies of Granbergs application notes.
> Or if anyone has other sites that sell mobile amps
>that would be great. I have a few so fare SGC, Worth-More, Ameritron,and
>Henry... Any others would be great!...
Not much else left.

Just to be different I collect nothing but QRO mobile HF amps.

To the above you can add:

Metron - No longer made.

Tokyo Hi-Power another 8 device unit but difficult to find a dealer.

Don't touch the Ameritron, it's a pile of junk.

The SGC's a nice unit but runs hot if you're into RF processing. You
also have to watch your antenna matching as it will trip out.

Go for the Henry, rated at 750w pep out, probably best of out of the
currently available crop.

Nearly forgot the Ten Tec, but somewhat expensive for 500w.

I've melted two BB3 160m Screwdriver coils so if you're going to run
power on the low bands run a Bugcatcher or Screwdriver who's factory
will guarantee no burn out!

Not only would they use them, they do use them. Take a look at the MA-561B government issue portable antenna kit. Its a horizontally mounted Bilal with a fiberglass telescoping mast all packaged up with its own green duffle bag. Standard issue with the 1088th Signal Corp.

> I doubt that it would stand one erection and take-down by a couple of
GI's.

No one ever said that the government is/was smart.

> Perhaps you are referring not to actual service military applications but
> to amateur stations in the MARS service.

Nope. MARS stations use whatever they can get their hand on. Very few MARS stations actuyally use military reissue. Conversely, the military has several standards during normal operational status.

> They are pretty flimsy devices, you know . . .

No one said that they wer'nt. I think the original poster was concerned about the performance of these antennas of which they perform perfectly, if one chooses to use them in the application that they were designed.

Who in their right mind would ever expect one of these antennas to perform like a Cushcraft Triband beam, or even attempt to compare them to one???

1680. Zo formula for line in thin dielectric??

Message-ID: <3832adca.0111081120.791f2242@posting.google.com>
Source record: 155033

Hi all,

Does anyone out there have a formula or reference for finding the impedance of a two-wire line, where the wires are rectangular cross-section and embedded in the middle of a thin plane of dielectric? Imagine, for instance, a couple parallel traces embedded in the middle of a thin circuit board, where there are no ground planes and the board thickness is about the same as the edge-to-edge spacing of the conductors, and the conductors are around 1/3 the thickness of the board.

Of course, the formula for one conductor working against a ground plane, where the conductor is embedded in a thin sheet of dielectric which is perpendicular to the ground plane, would also work.

Cheers,
Tom

Heh, heh... the toilet paper that your wife buys must be a lot higher quality than the stuff my wife buys.

When I was a lad we used pages out of Sears catalogue, tough to wind coils on that eponyomous book!

Or maybe it's just British toilet paper versus American toilet paper... my wife's toilet rolls just wouldn't stand
up to such a treatment.

Come to think of it... my poor old "tush" can't take it anymore either, I think I'll ask
her to start buying more upscale paper.

Reg et al:

Not all antenna experimentation is neat and scientific.

Here's my experience working with "stealth" vertical all-band antennas in a deed restricted neighborhood a few years ago.

In this situation I was reduced to stringing "invisible" wire upn in some old Southern Yellow Pine trees. This Southern Florida back yard had about 5 such tall pine trees, mixed in with a few Sable palms. The community didn't want any ugly antennas messing up the sub-tropical beauty of their pine and palm forest.

My quantitative efficiency results were gleaned from received signal reports obtained from "on the air" comparisons that I made with an "invisible" vertical wire strung up along the trunk of of one of those old 60 foot Southern Yellow pines located a few feet from my ground level radio shack window. Late one afternoon, a month or so after moving in, when the neighbors were not home, I threw a monofilament fishing line led with a small lead fishing weight over the highest branch I could reach in that Pine tree. Then later after dark I pulled the longest "hidden" wire I could up the trunk of that pine. It was probably about 35 to 45 feet long, and number 26AWG stranded copper.

I don't know how long it actually was... Heh, heh... as long as my thowing arm could make it. I then put out one radial in the garden/back yard to work the tree trunk wire against, again I don't know how long the radial was because it snaked all over the place. Then using a home brew antenna tuner I tried to work low bands [80, 40, 30 meter] dx with that set up.

Didn't get out of the backyard for days, and when I finally did raise a QSO I did it by first using BellSouth and phoning a ham about 20 blocks away. He could barely hear me. Many many local advisors allowed I should add more radials... and so I added one more, then another, etc... snaking them around in the gardens while I was "weeding", until I got up to 4 radials... Still nothing, zip, nada... no one heard me outside of the local neighborhood.

So then one night, I pulled my monofilament loop down from that old Pine tree and hooked a single 20 -25 foot "top load" wire to try to make that invisible vertical into an invisible "inverted L". I did this with a lead weight and a piece of monofilament connected to the top end of that hidden wire vertical, and then I threw the weight over another nearby pine tree to make my inverted-L. Adding that simple one wire top load was a lot easier than hiding radials in the back yard.

Then, wow! I commenced to work lotsa dx... worked about 100 countries on various bands with that "hidden" top-loaded antenna, [80-40-30m].

Since then I have always been a believer in top loading verticals.

Earlier today, someone put the URL for a "Snake-Oil" detection scheme on
the net.
it was:
http://www.bromleyinst.demon.co.uk/pages/soil.htm

Reading the "EH" antenna site put the Snake-Oil description right in the
proper context. It was almost as if they had been written together, with
the URL above containing the recipe by which the "EH" antenna site was
constructed.

You can look at reviews of antennas by hams that own them at www.eham.com.
The Cubex Quads are listed there too as are lightning bolt and Gem Quads.

You can work dx on the dipole, but the vertical will be best. I once
was talking to a guy in VK on 40m. I was using my usual 80/40 parallel
dipole setup I think. "This was years ago". We decided to try 80m as a
test. I had no problems at all working him on 80m, although the signal
level was not quite a strong as 40m. I might have lost an s unit or
two when we went to 80m. I was only using 100w on both bands. The
biggest part about 80m, is being in the right place and having a
fairly quiet band. Very little dx is worked on 80m from the US, except
in the dx window area around 3790 +-, and on the lower part of the cw
band. "3500-3550" So if you didn't listen in those spots, it's
unlikely you will hear much dx. I remember when I first got a ticket.
That year was real quiet on 80m. I used a low 40m dipole probably 20
ft off the ground and was still able to hear big roundtables of dx'ers
on 80m all over the world with that half size dipole and an old HQ-110
rcvr. I would think I would have been able to work most of them with a
decent 80m dipole and maybe a little juice. "I was a novice stuck to
cw, so couldn't try". But saying all that, a good vertical will be
much better. MK

Hi Chris

I use a linear-loaded inverted V, doesn't take up much space, made of simple wire, not real noticable and has outperformed everything else I have ever tried in the space I have.

The directions to build it can be found at http://archimedes.galilei.com/raiar under the Amateur Radio section on Antennas, if you care to give it a gander.

Dunno, small in size and efficient on 160m usually don't match. If you had a short vertical over half a zillion radials it would do ok, but thats going to likely be unfeasable. In your case, I would probably try to string an inv L, or add clippable loading coils to the G5RV so it could decently work 160m. If you added coils, you would want some extra wire on the ends to add as capacitive loading for it to work. So it might end up fairly long. But the directions of the strung wires would be fairly uncritical. You might also be able to short the feedline of the g5rv together and run as a top loaded vertical. The problem with this is the coil losses in the tuner would add up if the total length is quite a bit shorter than a 1/4 wl. Would be appx 61 ft plus the length of your feedline if the g5rv is a 102 ft version. I wouldn't expect to set the world on fire on that band in your situation. I find it hard enough just on a normal city lot with a full size Z dipole, and assorted inv L's etc. Naturally , the noise level will play a big part in how it works for you. On the quiet nights, you might do ok, on the noisy ones, it will be rough. If you have no radials or few of them, a longer than 1/4 wl inv L will work better overall." 3/8 to 1/2 wl" You get the max current point up off the ground. A 3/8 wl will only need a variable cap to tune out the

reactance. MK

Thats about it. Most of the big guns are running beverages, short
vertical receiving arrays, receiving loops, etc. I'm in the same boat
right now. I don't hear dx worth beans on 160m as I don't have any
good receiving antennas yet.
You want to talk to W8JI about all that. But haven't seen him around
in a while. MK

Peter- My old copy of the Mech Engineers handbook gives the order,
Silver, Copper, Gold, Aluminum, Tungsten, Molybdenum, Zinc--- Copper and
Silver are close, with Gold about 1.5 times the resistance of Silver,
and Aluminum just a little more. Tungsten, Moly and Zinc are about 3
times as resistive as Silver.
Gold's charm is is resitance to oxidation, not to flow of Electrons.
(but- you will NEVER convince the average person that this is it's
charm!) From an Econo-technical view, it's also cheaper to plate than
many other protectors.

I have decided to run a semi permanent coax at my apartment. At the last minute, my friends have talked me into RG8M. I bought a 50 foot complete cable from Radio Shack.

I have the paint to paint the cable to "hide" it. The reason that I want to do this is that my rig is near a window. I need to snake the feedline over to a deck as I am on the second floor. The wall kicks out a few feet to make way for a utilities. Since I cannot reach out, does anyone have any suggestions as to how I might mount the fedline or keep it from blowing around?

This message describes the rec.radio.amateur.*, rec.radio.cb, rec.radio.info, and rec.radio.swap newsgroups, as well as their Internet mailing list counterparts and complements. It is intended to serve as a guide for the new reader on what to find where. Questions and comments may be directed to Jeffrey Herman, KH6O, jeffreyh@hawaii.edu, or Paul Schleck, K3FU, pschleck@novia.net.

This message was last changed on 14 March, 1998.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions were held on the mailing list, and sent to the mailboxes of those who had signed up for it. When the Usenet software was created, and net news as we now know it was developed, a newsgroup was created for hams: net.ham-radio. The mailing list and the newsgroup were gatewayed together, eventually.

Over the years, as the net grew, the volume of discussion became progressively higher. First one by one, and then as part of two reorganizations, what was once one group became many. In the process, developments elsewhere on the net were reflected in the groups as they were created, most notably the change to place all of the ham radio groups in one hierarchy.

The collection of newsgroups continues to grow as more people join the net, and as more topics of discussion gain volume, I expect to see more groups be created as well. This follows what is happening on the rest of the net.

Nearly all of the radio newsgroups have corresponding mailing lists, the notable exception being rec.radio.swap. There are also a few mailing lists that don't have newsgroups.

The Current Groups
==================

It's important to post messages to the group that's appropriate for them, and not to the groups that aren't. The whole idea of having different newsgroups is so that folks who aren't interested in, say, homebrewing, don't have to wade through messages about homebrewing on the way to read about Field Day. Posting appropriately is just good etiquette.

The rec.radio.amateur.misc group is the catchall. It is what rec.ham-radio was renamed to during the first major reorganization. Any amateur radio-related message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, was removed on September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there. To answer a frequently asked question: No, there is no mailing list that goes along with this group. If you can't read Usenet news directly, you're out of luck.

The group rec.radio.amateur.policy was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate - it's now legal to order a pizza on the autopatch, if you're not in the pizza business - as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The group rec.radio.cb is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information

posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently David Dodell, WB7TPY. The email address for submissions to the group is rec.radio.info-moderator@primenet.com. Inquires and other adminis- trivia should be directed to rec.radio.info-request@primenet.com. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups r.r.amateur.antenna, .boatanchors, .dx, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas, the older tube based amateur, military, and commercial gear, commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is NOT the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter. The .dx group is devoted to long distance amateur communications. Each of these subgroups has its own charter and FAQ; please refer to the archives to find these documents.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

Mailing Lists
==========

In addition to the mailing lists that mirror the Usenet newsgroups, there also are a few that stand alone. These cover specific areas of ham radio, and discussion is focused on just those areas. PLEASE BE SURE TO SAVE THE WELCOME MESSAGE YOU RECEIVE AFTER SUBSCRIBING -- IT WILL CONTAIN IMPORTANT INFO REGARDING UNSUBSCRIBING!

The cq-contest mailing list is for discussions of contesting in ham radio. To join, send an email to cq-contesting-request@contesting.com.

The DX mailing list covers the finer points of DXing. This one is also joined by mailing "subscribe" on a line by itself, this time to dx-request@unbc.edu.

There's also a VHF mailing list, for VHF operators of the weak signal persuasion. You can join this one be sending "subscribe vhf" on a line by itself to vhf-request@w6yx.stanford.edu.

The QRP-L list is devoted to building and operating gear at low-power outputs. To subscribe, send an email to listproc@lehigh.edu and only write: subscribe qrp-l Your Name.

The TopBand e-list is devoted to all areas of operation on 160m. To subscribe, send an email to majordomo@contesting.com and only write: subscribe topband and follow the instructions you'll be sent. This site, contesting.com, also hosts a couple dozen other ham-related e-lists. Use the above address, and only write: lists to get the entire index.

The Boatanchors e-list is devoted to the older tube-based ham, military, and commercial communications gear. To subscribe, send an email to: listserv@listserv.tempe.gov and only write: subscribe boatanchors

For homebuilding transmitters and receivers using tube technology, there is the Glowbugs e-list; send an email to: majordomo@piobaire.mines.uidaho.edu and only write: subscribe glowbugs <your@address.here>

The VHF DX discussion list can be accessed by sending an email to: majordomo@blacksheep.org and only writing: subscribe VHF-DX-discuss.

We now have a list devoted to amateur radio history. To subscribe, send an email to: ham-radio-history-subscribe@egroups.com - leave the body of the message blank.

Qth.net hosts over 100 ham-related e-lists, including lists devoted to each state, manufacturer, mode, band - too many to state here. Send an email to majordomo@qth.net and only write: lists to get the complete index.

For one of the most complete indexes of email lists, see the excellent web site http://pw2.netcom.com/~ac6v/pageae.html

Please do NOT send subscription requests to the mailing lists themselves; that doesn't work very often, and is very annoying to those on the list. Also, please keep your electronic mail address current with any mailing lists you subscribe to, as dealing with returned email is a nuisance for the person maintaining the mailing list.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

Hi all,

comparing two antennas of the same size, one with a capacitive top loading
and the other with inductive base loading I remember a rule of thumb that
said that radiation resistance is higher by a factor of 4 for very short
antennas. The top head antenna has current distribution that is almost
constant over its length wereas the base loaded antennas current decreases
linearly when move from its base to its top. Plotting the two
distributions over position on the rod and calculating the areas under
the curves the top loaded antenna's "current area" is twice that of the
base loaded antenna. In combination with energy conservation this leads to
the above rule (at least for very short antennas with less than lambda/8)

1700. Re: Problems with thesis "Multiband antenna for mobile communication"

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-09 09:20:01 UTC
From: rafael <rafahol@hotmail.com>
Message-ID: <9sg724$65v$1@news.tudelft.nl>
Source record: 155053

Hello Clark,

Thanks for your excellent answer of my question but I will put some comments below that are still not solved for my thesis (I will explain in detail the specifications of my thesis).

The title of my thesis "Analysis and Design of a Multi-band antenna for mobile-satellite and radar communication".

Summary: This thesis concentrates on analysis and design of a three-band antenna element at L-band for mobile communications. In the past the antenna elements used for the telecommunication were designed to have an optimal performance at the desired frequency. In order to ease the roaming and improve the performance the antenna elements for the present and the future mobile- and radar communication however should be capable of transmit and receive at different frequency bands. The three bands that must be focused on are:
GSM 1800 -> 1795 MHz
UMTS 1 -> 1960 MHz
UMTS 2 -> 2140 MHz

The criteria are based on the low input reflection coefficient (S11 < -10 dB) and to have the same gain for different bands (gain > 4 dB) and the flexibility over the control of the operating frequency.

Because dipole antennas and helical ones are not very well suited for my thesis based on a table with advantages and disadvantages (I started a study of literature regarding different type of multiband antennas), I started to focus my solution in microstrip antennas. Reading a lot of literature about multiband patch antennas, I found a very interesting one "Fractal multiband antennas for mobile communication" and the Sierpinski gasket dipole antenna so I searched further for more information. At the end I had so much literature about these called so magic fractal antennas, that I contact to Carles Puente who investigated these antennas in UPC Barcelona. He send me his thesis so I analysed the theory behind these antennas because I thought that these were just the solution for my three-band patch antenna because they satisfy conditions which has to meet a multiband antenna.

A new type of antenna that seems to be a solution for my thesis, has to meet the followingr requirements:
1) It must be symmetrical about a point
2) It must be self-similar, having the same basic appearance at every scale that is, it has to be based on fractal technology.

CONCLUSION: I would like to design a three-band antenna based on fractal structure and as solution a Sierpinski gasket like antenna would be very

welll suited for this kind of purpose.

Because till last month I couldn't achieve the same results of C.Borja and Carlos Puente to achieve same results of his measurements regarding one IEEE paper and my simulations with the software package ADS of HP Momentum, I become more and more anxious in how to solve my problem. I started to a study of other software packages that maybe could solve my problem and study between MoM and FTDT but later on seemed that other things were not done very well. After having spoken a lot with my tutor and after having had contact by email with technical persons of ADS, I got better results because it seemed that I hadn't drawn very accurate the Sierpinski configuration. The problem lied in the fact that the current couldn't move from the bottom to the top and therefore no resonance frequencies appeared.

This problem is now solved but this was only a purpose to see if ADS was capable to handle this type of antennas. Now I have to change the configuration for achieving the resonance frequencies based on my thesis and that is more diificult because ADS can't optimize these antennas in my case (there is no license). Therefore I had to search for a method for achieving the three resonance frequencies with such a structure. Because in most of the literature they explain only the multiband behavior of the Sierpinski monopole instead of the Sierpinski patch antenna I didn't know if this also could work as microstrip antenna.

In one the articles I read they explain that a three-iteration Sierpinski monopole antenna in fact is equally to three different bowties (different heights) and therefore starting from this point one could design every kind of monopole antenna based on this fact and specific requirements. Given three frequencies one designs three equally sided bowtie antenna and integrates them to one structure so that one antenna gives the same behavior as the three antennas.

What I know wanted to do is using the same procedure for my thesis to solve my problem to design my three-band multi-band antenna. Because it seems that the heighest subgasket takes care of the lowest resonance frequency and each lower subgasket for the upper resonance frequencies maybe one could change the structure so to achieve the three bands.In this case each gasket would equal to a triangular patch antenna instead of a bowtie in the monopole configuration and therefore designing three triangular patch antennas at the mentioned resonance frequencies and integrating them in a Sierpinski pattern maybe would achieve a three-band patch antenna in one configuration.

This is what I am still analyzing and I hope that my questions and problems are more clear for you.

Rafael

Bill:

Gold is almost universally used on PC Board edge connectors, "plated with x-microinches of xx gold", etc...

I presume then that usage of Au is for it's anti-corrosion capabilities and not it's lower conductivity.

Could any tell me why I would get rf feedback through my coax even though coax and plugs are sound,and there are no breaks,shorts opens in ant?

1703. RF ground system durability

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-09 14:21:16 UTC
From: Jan Ditzian <ditzian@alltel.net>
Message-ID: <1103_1005315676@Jan>
Source record: 155056

I just erected a 160-meter version of the parasol antenna described by Christman in October 2000 QST. The next step is a ground system. Ultimately, I hope to install a large number of 1/4-wavelength (135-foot) ground radials. I have room for elevated radials, and I intend to use some early on, but I would like to clear the area after a while and remove the elevated radials when there are enough ground radials.

My initial questions have to do with the wire for the ground radials (not the elevated or gull-wing radials). I have some pvc-jacketed #14 wire, but I have been given some unjacketed copper-clad steel #8 wire. I have heard that unjacketed copper-clad wire, installed on or under the ground, deteriorates over time, and becomes less suitable as part of a ground screen. Is this the case? Where can I find authoritative information about this situation? How long is the expected life of on-the-ground copper-clad radials? Is the oxidation of the copper plating really a hindrance to RF current that would otherwise flow in the wires?

With regard to the elevated, gull-wing radials: If it turns out that I should not use the unjacketed #8 wire for the on-the-ground radial system, is there a disadvantage to using it as part of an elevated system? I will string these wires through many trees, and the process will not involve climbing a ladder and gently placing the wires on insulators, it will involve throwing the hank of wire over a branch, grabbing it when it falls, and stumbling down a steep hill to the next tree, while cursing the blackberries, raspberries, poison ivy, hawthorne trees, and wild rose. I have strung radials here a number of times in the past, and have never succeeded without blood loss. At one radial per trip, injury at 100% per trip, and 120 radials, I am arranging for a permanent account at the blood bank.

=======================================

The theoretical 4-times increase in radiation resistance for top loading of a short vertical antenna is impossible to achieve. It may approach that value when the capacitance hat is about 1/2-wavelength in diameter !

And if it was achievable it would NOT mean efficiency increased 4 times. For example, if the unloaded radiation resistance of a short antenna is 5 ohms and the ground loss resistance is 2 ohms, then efficiency is 71%. Even if, by top-hat loading, radiation resistance increased to its theoretical maximum of 20 ohms efficiency would increase only to 91%, equivalent to 1.1 dB or about 1/6th of an S-unit which most people would not notice even if they were looking for it.

In the case of coil loading the situation is worse. Although a top coil-loading coil may substantially increase radiation resistance, if the coil loss resistance is even greater then efficiency may actually fall.

In general, with the usual sort of ground loss resistances, to significantly improve radiating efficiency a very large, inconvenient top-capacitance hat is needed.

And with coil loaded antennas, with the usual sort of ground loss, the optimum coil location is just over half way up to the top. Furthermore, at that height, the improvement over bottom loading is often not worth the trouble. Another disadvantage - a coil loaded short vertical is a one-band antenna.

To analyse behaviour of capacitance loaded vertical antennas download from website below program TOPHAT1.

To find the most efficient location of the loading coil in a vertical antenna download program LOADCOIL and slide the coil up and down while watching efficiency.

Depending on amateur band, for a given height, top capacitance is usually the winner - provided nobody objects to a gigantic set of radials 9 feet above your car roof.

You will get many suggestions from others.
Don't forget that the coax is in the near field of the antenna, and could be picking up energy from the antenna. A few RF snap on torroids may help that.

Correct, very short means Hertzian dipole (or monopole if there is a
"Hertzian monopole". The last digit behing the comma is always a problem
with this kind of "hand waving" argumentation. Gerhart Janzen gives
approximative formulas in
his book "Kurze Antennen" (don't know if there is an english edition) for
monopole antennas less then lambda/10 long. The base loaded is R_s=395
square(h/lambda), the capacitive one is 1580 square(h/lambda) (if I
remember right), I don't remember about the size of the error compared to
the "exact" solution, but I can look up.

> And if it was achievable it would NOT mean efficiency increased 4
> times.

Correct, since eta=R_s/(R_s+R_losses), meaning if I have already 80 %
maybe not worth the effort to half the R_losses.

For example, if the unloaded radiation resistance of a
> short antenna is 5 ohms and the ground loss resistance is 2 ohms,

I hope I could not be misunderstood in this manner, since I don't believe
in "inductive top loading", I only wanted to compare "inducive base
loading" and capacitive top hat.

> significantly improve radiating efficiency a very large,
> inconvenient top-capacitance hat is needed.
>
> And with coil loaded antennas, with the usual sort of ground loss,
> the optimum coil location is just over half way up to the top.

There is a graph in the quoted book showing exactly the same. Janzen
assumes he can achieve a given Q and moves this lossy coil up the
radiator, calculates the needed inductance and than the efficiency, graphs
in my edition of the ARRL antenna book look pretty much the same.

Perhaps, I don't think you could ever find anything authoritative
other than your own experience.

> ground copper-clad radials? Is the oxidation of the copper plating really a hindrance to RF current that would otherwise flow in the wires?

I don't believe so.

The most common ground rod I've seen is a copper-clad steel rod. In
my soil conditions it is fine (the copper turns dark brown and stays
that way for more than 20 years thus far). I have heard that in
some soil conditions the copper is eaten away with some rapidity.
However it seems that the steel wire would be better in those
conditions, as for such they usually recommend steel ground rods.

It seems the highest use for the copper-clad steel would be for wire
antennas. (It is usually stronger than solid copper.) But if you
have no intention of using it for that purpose, I'd use it for
ground radials.

I am not sure what you mean by "r-f feedback through my coax" but keep in mind that the outer braid of coax is an independent conductor not related to the differential-mode operation of the coax.

This means that a common-mode current can exist on the outer braid and that current might be the cause of some problem that you are having.

Usually, a choke or current balun will reduce or eliminate such currents.

Hello:

In the past I have used AWG#26 stranded copper wire which used to come with a Radio Shack SWL antenna kit. I don't know if RS still make or sell this kit, since I haven't needed an invisible antenna for a few years. But... this neat Radio Shack product, primarily aimed at Short Wave Listeners contained a farily long (100 ft if I recall) length of bare stranded #26 copper wire, a couple of insulators, a couple of standoffs, and a length of insulated number 26 wire to be used for a "lead in".

For my stealth ham antennas, I just used the #26AWG stranded copper piece of the kit and usually held it up with monofilament fishing line. The stranded #26 copper, although bright when new, quickly oxidizes into an almost invisible non-reflective wire that simply cannot be seen against the sky, even in bright sunlight, when up 25 feet or more. Neighbors stood and talked with me right underneath it for several years without ever noticing it was there! The stranded wire has a great advantage over the solid enamaled wire, since it is very flexible and not subject to destructive kinking, etc... I used to run 200 Watts into those antennas with no problems.

I'd like to know if RS still sells that antenna kit. Over the years I bought 3-4 of them just for that thin stranded copper wire. They should sell the #26AWG stranded copper wire separately, it'd be a good seller.

Hi Rafael,

We will take the frequencies of interest first:
>GSM 1800 -> 1795 MHz
>UMTS 1 -> 1960 MHz
>UMTS 2 -> 2140 MHz

If I scale these down to HF by a division of 100 and consult my pages
on fractals (not just sierpinski's) built in the air (as opposed to on
a substrate):
http://members.home.net/kb7qhc/antenna/fractal/Constant%20Wire%20Comparisons.htm
It reveals a table of resonances for a constant length of wire
employed for any design. OR If I were to view those same geometries,
but now only constricted to a constant height (makes for large
antennas by the way):
http://members.home.net/kb7qhc/antenna/fractal/Constant%20Height%20Comparisons.htm
ONLY the Koch Quadratic comes close with just two resonances and it
would be a fantasy to hope they both land on or could be force fitted
to them.

This is the fantasy of fractal scientists (sic) in that they report
multi band operation without really describing that "multi-band" is
shorthand for what is commonly found even in the simple mono/dipole.
On those same pages you will find a reference antenna, a monopole,
that shows 5 band operation! So What? Having said so (as do the
fractalists) does not make it very useful. I would point out by the
way that the monopole (or dipole or loop) satisfies every fractal
quality you list as necessary (they are extremely self-similar at ALL
scales! Such is the laughability of these qualities that
"distinguish" fractals.).

I can anticipate an argument that additional iterations will serve
your needs. To answer that lame observation I would offer:
http://members.home.net/kb7qhc/antenna/fractal/Constant%20Fractal%20Comparisons.htm
Here you will note your sierpinski's resonances through 6 iterations.
And to offer as a basis of comparison, that page also reveals other
geometries that are varied through progressive iterations. You will
observe that neither the sierpinski, nor any other geometries acquire
any benefit of compression; and in fact LOSE resonances. Yes, they do
get smaller as they iterate, but that is not part of the equation. If
I had iterated these same geometries against a constant height
(allowed them to grow, as it were), then yes, we would observe more
resonances. And yet they would still offer very few clustered in the
narrow band of frequencies you assign above. Sorry.

You are really in trouble. To obtain the multi-banded operation you
seek really requires a large fractal design. That is 4 to 10
wavelengths in size! At the "small" end of only 4 wavelengths you may

find individual resonances that peak in your bands (maybe). At the "large" end of 10 wavelengths, the design will become broad banded enough to encompass these and every frequency through 4 GHz (if you can transform an R of 300 Ohms). This last observation is shown rather poorly at my page:
http://members.home.net/kb7qhc/antenna/fractal/Wide%20Band%20Comparisons.htm
and in fact is supported by sierpinski, but is displayed in a one-time model that breaks my standard pattern of design. This page is meant to be illustrative of the scale of the problem.

The question to be answered at this point:
Does the addition of the substrate offer any potential to compress resonances? If you cannot answer this question, or if you cannot find a solution to this question, there is no point going further. Note, there is nothing in this question that demands a modeler, and in fact, given the problems you suffer, it would seem that that pursuit is a fool's errand. You need only build two example antennas. One in free air with known characteristics and the second, identical geometry, on a substrate for comparison.

If you find compression, you can go forward and you have something to model. If you do not, then you need to think "outside of the box." You can still use fractals, even sierpinski's if you really want to handicap yourself (why, I don't know, the sierpinski is not really that useful). You should think instead of one for each band, with all excited by a common driver (a feed loop say - even if that too has to be fractal - sheesh).

Well, Rafael, you have put up with my rather brutal assessment; and I hope you can resolve your needs with these comments. All things are possible.... I think your solution is found in my last comment above about multiple fractal elements. This is the standard commercial answer in real life.

That is correct. Some of the early PCs used unplated connectors and
often they would quit tuil you would unplug the cards and reseat them .
Often they need a rubbing with a pencil eraser . Heathkit homebuilt
computers seemed to be bad about this. Seems that they would send
replacement connectors for the motherboars for this reason.

No, it is for the anti-corrosion properties. After all , how many times
do most computers have the cards changed out ? Most are luckey to get
inserted more than once.

sounds like a beer commercial... 'less corrosion!' 'less erosion!' 'no, its better conductivity!' how about all of the above... gold is just an all around good material for electrical contacts.

Reg, Ralf, Roy:

I just thought of an interesting question re: ground mounted verticals.

What about an upside down ground mounted vertical versus a normal ground mounted vertical.

An interesting question/comparison about ground mounted verticals would be...

Design a short ground mounted vertical, mounted say a small fraction of a wavelength [a foot off the ground at HF say] with some [insufficient] number of radials... and calculate it's efficiency.

Then turn the design upside down... with the tip the same height off the ground as the original ground plane, now top hat and re-calculate the efficiency etc...

For the same total amount of wire [and aluminium] which one is the winner and by how much...?

I think I'll go fire up EZNEC and find out...

The upside down ground mounted antenna, feed the coax up through the flagpole and feed it at the top...

Could be interesting, eh?

There is a whole science on "contacts". I once had to scratch the surface on this topic. Contacts carrying low currents are vastly different than contacts carrying high currents. IIRC, gold is not good for high current contacts, silver is better. It gets deep.

I got a bit below the surface on this topic some years back. Right after the release of the fixed price for gold, it rapidly went from $32/oz to about $1000. So all the switch and connector manufacturers were scrambling to find lower cost materials. I'll make a very long story very short: There's no substitute for gold for dry-circuit (low voltage/current) contacts, switch or connector. If you use any other material, sooner or later it WILL fail. Period.

J. is right about low and high current contacts. Switching high current is relatively easy, since arcing burns through and/or blasts away surface contamination. Silver is the best material for this purpose. Besides being an excellent conductor, it's also an excellent thermal conductor, so the heat is spread away from the point of contact. Dry circuit switching is much more difficult, because any surface contamination or oxidation interferes with performance. Take a look at the little toggle switches in your junk box. You'll likely see some that say something like "1A 125VAC" or thereabouts. (Some I have are 2A 250V or 5A 120V.) These have silver contacts and will sooner or later cause problems if used to switch dry circuits. (We can often get away with it for home projects, but if you put a few thousand of them out into the field in all sorts of environments, I guarantee that the customer support phone line will start ringing before long.) Some other switches say "0.4 VA Max" or "0.4 VA 20V". These have gold plated contacts and will fail quickly if used for switching any power. The gold will be blown off the first time the switch is closed, and the underlying material will burn away shortly after.

Some high quality swiches have gold plated silver contacts, making them sort of universal. These can be used for either application. But once used for a power application they can't be used for dry circuit switching, since the first time switching power will remove the gold. These are often marked with the higher power rating, so the only way to identify them is by looking at the manufacturer's specifications.

Like J. said, it gets deep. I had the privilege and good fortune to consult with a very knowledgeable chemist (Jim Smiley) who was a real expert on platings and corrosion, at a company (Tektronix) that was truly committed to reliability and quality. It was really educational. But if you just remember that for dry circuit contacts, you should always use gold, you'll save yourself a lot of grief.

Looking out my office window in Somerville, NJ, several years ago, I watched a crow make a very unfortunate landing on a power line transformer on Rte. 202. Lots of light and a puff of smoke! The power was in that part of town for several hours.

|around good material for electrical contacts.

Well, there is gold and then there is gold. Different alloys and plating techniques are used depending on the application. Circuit board edge contacts are alloyed for increased hardness and wear resistance, gold traces on MIC substrates are purer (softer) gold for good bonding properties.

Gold can be dissolved by solder so component leads that used to be gold (when things were plugged into sockets) are now specified with tinned leads.

Gold also migrates into some base metals unless a barrier layer of another metal (usually nickel) is used. This can cause a problem in RF applications if the gold isn't thick enough.

Trust me, I know this from agonizing experience <g>.

i just purchased a Cobra 148 NW ST for use in my pickup. the antenna
that i got also a Cobra doesnt work very well at all.

i know that the knowledgable people here can help me out, what antenna
would you use?

thanks in advance

Yes, they still sell that antenna kit but it comes with, I believe, 12 gauge
wire.

CW:

I hope they have those gold connectors on the 12 guage wire. Imagine how well an antenna made out of "monster speaker cables" with gold plated connectors would work slung between two trees and fed with really really heavy coax. If it makes your stereo sound that much better imagine what it would do for DX from Oceania!

I have a QST article somewhere where a guy made a vertical like that.
The idea being getting the max current point at the top instead of the
bottom. In the article he said it worked pretty well. You have to use
a pretty good insulator being the bottom is then the high voltage
point. This QST was in the 50's-60's I think, but I'm not sure. I'd
have to dig it out. He used a full 1/4 wave though I think. A bobtail
curtain would be sort of a phased version of this. The current max is
at the top on those, which me thinks is a major reason those seem to
work so well on the lower bands. MK

1734. Re: RF ground system durability

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-10 12:28:09 UTC
From: Les Kramer <wa3sgz@mindspring.com>
Message-ID: <9sj6h6$q8c$1@nntp9.atl.mindspring.net>
Source record: 154986

Hi Jan,

I am a materials/corrosion engineer by profession, but I have no experience with verticals that use radials so my comments may not be germane to the RF part of things.

At least two major things control corrosion underground - the soil conditivity and the presence of stray electrical currents for your home's electrical service and other sources. Unless you test for these attributes like utility companies do (i.e., with underground pipe), the actual corrosion situation will be hard to access. These tests to do a site survey take specialized equipment and are probably expensive. You have probably heard people talk on this NG about adding some salt to the bottom of a ground rod to lower ground resistance - what they are actually doing is increasing the soil conductivity, maybe increasing the ground rod corrosion rate, and poluting the ground water with the salt ions.

Copper is a pretty corrosion resistant material and here in Florida, the main water service to my home was actually a copper pipe coming out of the ground (i.e., until I replaced it with a plastic line when I added a shutoff valve). The degree of corrosion resistance of most metals really occurs because due to their ability to form a stable, thin,. surface boundary oxide. Since iron oxide is a friable, non continuous surface film and copper oxide is a good continuous film, the life underground of your 8 gauge copper clad wire depends on the thickness of the copper clad outside layer. These "Copperweld" wire are made two ways - coextrusion of the copper over the iron and electroplating the copper onto the steel. The electroplating is highly undesirable because the copper layer is so thin (i.e., several thousandths of an inch) so little corrosion resistance is present. I have to change out wire antennas made with this material in rainy Florida every 3 years or so. If your copper layer is thick (say 1/4 the wire diameter in cross section - I don't know the range of thicknesses resulting from the coextrusion method), this wire may be a reasonable underground radial. I would calculate the cross sectional area of the copper in the "Copperweld" type wire after measuring the copper coating thickness and compare it to the amount of area in the #14 jacketed wire. When you cut the ends of both wires to look at the cross section use an abrasive cutting method since the pinch of a wirecutter will smear the ductile copper layer. For the #8 Copperweld, the area formula is Pi*R2(copper) - Pi*R2(steel core) where R is the measured outer diameter of the respective metal layer. For the #14 copper wire, the area formula is just Pi*R2 for the copper wire outer diameter.

The bottom line of this discussion is that I would use the PVC jacketed #14 wire for the following reasons:

1.) The PVC isolates the wire from the variably conductive soil and stray currents in the soil thereby removing this concern until the PVC deteriorates in many years.

2.) Since manufactures always "optimize their metalworking processes for minimum use of the expensive component", I would bet that the #14 wire has more copper in it than the "Copperweld" if you bother to measure and calculate the copper cross sectional area.

3.) Once the "Copperweld" copper layer is penetrated, the steel core will begin to rust. The volume of the rust will be larger than the steel (i.e., the same reason that potholes form in roads and bridges when the rebar rusts) and the copper layer will be mechanical expanded to the point with time where a break will occur prematurely compared to the gradual or pitting corrosion of copper alone in natural soils.

I hope that this info helps.

GUD LUCK.

Tom,

No one else seems to have answered your question so I'll give it a shot.

Such a system will have dispersion, so if the dimensions are a substantial portion of a wave length in the dielectric, you will have to solve this as a more general wave guide problem. However, at lower frequencies you can approximate it as a quasi TEM mode as you imply. In that case you can calculate the inductance and capacitance per unit length. The inductance will not be substantially changed from the case where there is vacuum between the conductors, and in that case, the inductance and capacitance per unit length are related by sqrt(L C) = 1/c. If you calculate the capacitance per unit length between the conductors when the dielectric is vacuum (call this C_0) and the capacitance per unit length with the dielectric, the characteristic impedance will be pretty well approximated by

Z0 = 1/[c*sqrt(C*C_0)]

where c is the speed of light in meters/second, and C and C_0 are in Farads/meter. Similarly the velocity factor is sqrt(C_0/C).

To calculate the capacitance, you can use any number of electrostatic methods. The easiest method to program is probably a two-dimensional relaxation method on a square grid. A faster and more accurate method would be a boundary element method.

A quick and dirty method which may be accurate enough, would be to first find the equivalent circular diameter of the wires; there is an applet on my web page http://fermi.la.asu.edu/w9cf that will tell you this. You now have approximated the system with circular wires instead of rectangular ones. This approximation requires that the equivalent diameter be substantially less than the spacing or the dielectric thickness. Within this approximation you can replace the potential by the potential of two line charges at the centers of the wires.

For the vacuum case, if the wires have a diameter of d and a spacing of s, the potentials on the surface of the wires for a charge of lambda Coulombs per unit length, is

V1 = (mu_0 c^2/4 pi) [- 2 lambda ln(d/2) + 2 lambda ln(s)]
V2 = -(mu_0 c^2/4 pi) [- 2 lambda ln(d/2) + 2 lambda ln(s)]

so that the potential difference is

V = (mu_0 c^2/4 pi) [4 lambda ln(2s/d)]

where the first term is the potential from the charge on the wire itself and the second is the potential from the other wire. The capacitance per unit length is

C_0 = lambda/V = 1/[(mu_0 c^2/4 pi) ln(2 S/d)]

As a check, in vacuum the characteristic impedance would be

Z0 = 1/(c C_0) = (mu_0 c/ 4 pi) 4 ln(2S/d)

The numerical value of mu_0/4 pi is 10^(-7), and c is about 3 10^8, so that (mu_0 c/ 4 pi) has the numerical value of about 30, or

Z0 = 120 ln(2S/d)

which is the usual formula.

You can calculate with the dielectric by using an image charge expansion. That is, inside the dielectric, you can replace a dielectric boundary by assuming the dielectric is everywhere, and place an image charge reflected through the boundaries with magnitude (K-1)/(1+K) where K is the relative permittivity. Since there are two boundaries, the images give images. For each wire, you will therefore end up with a set of images spaced a distance t apart each one with charge (K-1)/(1+K) times the adjacent one. (For the potential outside the dielectric, you eliminate the previous images that are outside the dielectric on the side where you evaluate the potential and multiply the remaining charges by 2/(1+K).) The potential difference on the wires is approximated by adding the potentials of all the charges as if there is a dielectric K everywhere

V = (mu_0 c^2/ 4 pi K) [4 lambda ln(2s/d) + 8 sum_(n=1 to infinity) [(K-1)/(1+K)]^n ln(n t/sqrt(n^2 t^2+s^2))]

and the capacitance per unit length is

C = lambda/V

The sum should converge fairly quickly unless K is very large. You could code this up or put it on a spread sheet fairly easily.

The quick and dirty calculation drops terms higher order in d/s and d/t, so it will be a poor approximation if the dielectric is thin compared to the diameter. For your example you might get adequate results, but in the end you probably want to use one of the more general methods. The chances of me typing everything above correctly is probably close to zero, so you should check evrything carefully.

"Copperweld" is a trademark of LTV Copperweld, the maker of Copperweld products. Copperweld wire is a sandwich of steel and copper, with the copper making up a substantial fraction of the whole thickness. Copperweld wire doesn't have just a thin copper plating. You'll find this thin plating on some electric fence wires, but never on Copperweld.

Invisible antennas.

Well in my neighborhood, there are many quite young folks, who have vision much better than my "old eyes" can muster, and they could easily spot a 12 guage wire against the sky. 12 guage wire is good, but invisible it's not. Bare #26 begins to approach invisibility when up at 25 feet or more, but larger guages will show up. Heck... once in a pinch I've even used #30 for a few weeks, in a situation where invisibiltiy was paramount.

Les Kramer wrote:
"----the life of your 8 gauge copper clad depends on the thickness of your copper outside layer."

True, but I`ve never seen Copperweld used for radials. It is more expensive and harder to work with than ordinary copper wire. However, were Copperweld used for radials, I would expect almost unlimited life due to its very thick copper cover of the steel inside.

Copperweld`s steel core is for strength when the wire is suspended. Like the makers of baking soda, the makers of Copperweld will likely gladly sell you their product for any legal purpose, but why buy Copperweld for burial? The span between supports in the soil is very small.

For r-f transmission lines and antennas, Copperweld is ideal. Skin effect causes the r-f to have penetration limited to the surface of the Copperweld. Penetration is shallow as compared with the copper depth. Steel in the center of the wire gives it high strength. The steel is protected from rusting by the heavy coating.

Other than cost, about the only drawback to Copperweld is its springy quality as a result of the steel which makes it somewhat harder to work with than ordinary copper wire.

I should follow Br`er Reg`s example!

Would not the problem be basically the same as finding Zo for twinlead? L&C require adjustment for conductor shape, size, spacing, and the dielectric constant perhaps requires adjustment for a difference between polyethylene and fiberglass, or some other materials,

Don`t the common Zo formulas give guidance? Don`t you start with Zo = square root of Z/Y ?

Andrew wrote:
"Even just plain H2O for instance."

Pure H2O is an insulator. It withstands thousands of volts and passes negligible current. Add salt to water and it becomes a conductor. How good, depends on concentration of the salt. Sea water is assumed to have a conductivity of 5000 millimhos (siemens) per meter. The reciprocal is 1/5 ohm that might be measured between faces of a cube of one meter on a side.

The FCC has charts for soil conductivities between 0.5 and 40 millimhos per meter. the reciprocals are 2000 ohms to 25 ohms that might be measured between faces of a 1-meter cube. That range of soil conductivities probably covers any extensive patch of soil to be encountered.

The CRC Handbook gives reciprocals of conductivities of metals in micro-ohm-centimeters.

Reg surely jests, but in the US, a manufacturer, Guiberson, made air-cooled radial diesels that worked very well indeed.

Also, the biggest boon ever to hit the model aircraft hobby was the appearance of miniature diesels to replace gasoline model engines which were always plagued with ignition problems.

Right. You should be able to use the right length of wire with a banana plug into the coax connector as an antenna with no problems.

If some of the r-f output gets back into the right place in the right phase and amplitude in some low-level stage of the sender, it may create a new oscillator.

Shield with the box to prevent re-entry of the r-f to such a sensitive spot, and filter audio, power, and all other wires, except the output, for r-f.

==========
Yes Roy, it amounts to obtaining money (salaries) by confidence
tricks.
==========

Getting to the crux of the matter, it can be shown** the resonant
Q of a 1/2-wave dipole is given by -

Q = 1.29*(Ln(Lambda/2/d) - 1)

where Lambda is the free-space wavelength and d is conductor
diameter.

So bandwidth = Fres/Q.

Suppose we have an 80m dipole with a conductor diameter of 1mm = 18
AWG. Then Q = 12.4

If the conductor is changed to a pair of 1mm wires spaced 100mm = 4
inches, the effective diameter increases 10 times and Q decreases
to 9.4

So the result of having a pair of spaced wires is to increase
bandwidth by about 16% on either side of resonance which is not a
very noticeable improvement. The attention devoted to the effects
of conductor diameter is not really justified. But it does matter
in such cases as bandwidth of LF broadcasting antennas where the
audio spectrum is affected.

Same value of Q applies also to a 1/4-wave vertical. But whatever
the antenna, it is the bandwidth of the whole system which matters
and the overall response depends at least as much on the
transmission line and tuning arrangements as it does on the
antenna.

==========

** The Q of a transmission line is just the same as any other tuned
circuit. It is the ratio of inductive reactance to resistance. So
considering the antenna wire as a transmission line, which it is,
Zo and hence inductance can be calculated from its two dimensions,

length and diameter. The resistance involved is radiation
resistance. What else? If you are pernickety the wire loss
resistance can be included.

True- I put up a copper 26awg long wire about 100 ft long, and in the first soaking rain (NC) it got about 10 feet longer from the weight of the water on it.

OK Looking to build a wire antenna
The one that I would like to use is the wire antenna that uses the flat
300Ohm wire (TV) with the ends soldered together and run that to the radio.
My question is what is the difference between the flat wire antenna and the
bare wire antenna and which one will work better.

You're wasting you time with this yard-bird Wes.

No matter how he is asked (nicely or in more stronger terms) to QRT
this stuff he just keep spaming along.

I want to thank the four posters (sounds like an ad for a bedroom
suite) who sent information about the use of copperclad steel wires.
As usual, information that I assumed was irrelevant was important.
Here are some more facts:

- The wire is #8 copperclad. It weighs a bunch.
- It originally came from a railroad, went through typical
ham/surplus peregrinations, and wound up in western MD and then in
southwest PA.
- It is given to me in exchange for helping erect towers (my job
is to stand on the firm ground and pray for divine assistance while
someone else climbs the towers).
- There is a possibility that I will wind up with around 1000
feet of it, in 188-foot hanks.

- 1/4-wave on 160 is around 135 feet.
- #8 wire is pretty heavy stuff to use for antennas, but I am
willing to lay it on the ground.
- The stuff probably is not Copperweld (copyright), but the
coating is possibly more than just "a few thousandths" thick.
- My long-term goal is to be able to drive over part of the
ground screen with a tractor and a brush hog, rather than have to walk
under elevated radials.
- Elevated radials will probably shorten what is already a short
(65-foot) vertical section. I would like to get that height back.
- I do not seem to keep any antenna, except for the TH6DXX, more
than a few years.

This means that, given the lack of outright warning against using this
stuff for ground radials, I will probably use it. If I ever have to
PAY (what an ugly word) for ground wire to replace it, I will probably
go for thin (#20 or #22) PVC-covered wire, based on the comments that
I received. I will check it yearly, but my 160 country total is low
enough that a few years of decent function can mean a lot.

BTW, the antenna above this wire is a Parasol (QST, October 2000)

73 and I hope to see you all on top band,
Jan, KX2A

CW:

Agreed!

But when you are trying to hide an antenna in the pine trees, from next door neighbors and the Homeowner's Association busybodies, why then you can put up with #26. And... if you don't insist on pulling it tight, letting it sag quite a bit, it seems to stand up to really big blows. And... it's invisible.

Peter,

>What about an upside down ground mounted vertical versus a normal ground
>mounted vertical.
One day I was intending to try something similar on a 160m mobile.

At present I have 13'6" 3/4 loaded with very large cap hat and homebrew
Bugcatcher coil.

What would happen if I fed the coax up the centre of the mast to the top
of the mast, did away with the hat and used the vehicle body/chassis as
the hat?

If it worked at all it would be interesting to find out how much
inductance I'd need to resonate the antenna ANd where on the mast said
inductor would be located for max field strength.

Have used a spectrum analyser in the past for measurements from the far
field.

Any thoughts anyone?

Would it work at all?

Phil G4ZOW

Pure H2O doesn't conduct, but it doesn't take much dissolved salts and/or carbon dioxide to make it one. Over short distances, normal tap water will pass enough mA at our 240v mains to fry you.

For high conductivity, you want a salt that ionises strongly and has a high solubility in water - common old sodium chloride isn't bad. Try Google.

1768. Prg or Eq to calculate optimum 5/8 th antennas coils

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-11 23:11:02 UTC
From: johnber <johnber@optusnet.com.au>

Source record: 154921

Hi this is my first post to this forum..

I am involved with a community radio and planning to improve their
coverage.
I know everybody and his dog go for folded or helical dipole and stuff...
But I don't want to get involved with phasing harness and all...
just something streamlined and inline with the mast.
aiming more to a 5/8 and double 5/8 (double zepp. Or a collinear design)
I have been scouring the net for a good while to find a suitable site
or info in general about 5/8 eighth antennas and even though there is a
bunch of pages out there about how to find a design or length.

nobody seems to bother or know how to deal with the matching coil Why !
Is there something esoteric about it! some kind of "Black Magic" Maybee !

This one for example seems good: http://web.wt.net/~nm5k/10du2.htm

I just want to know if there is a prg out there in to which i give the
Frequency I'm interested in and spit out:
the best combination possible.

Length of radiating element
Optimal Characteristic of the matching coil for given frequency.
Diameter of coil.
height of coil.
Numbers of turns.
spacing between turns.
overall Length of coil with size of wire or tubing to be used.
Approx distance from bottom to feed point.

Variable input would be:
Type of radiating element:
wire (Portable use !) or Tubing single continuous diameter or Tapered
type and Size of material for the coil (wire - small tubing)
I think i have covered most of it.

This kind of information would certainly go a long way in improving the
image of the 5/8th antennas
I Understand that nothing is perfect and tuning would be necessary.
But getting the theory right in the first place would definitely help.

Thanks for any help.
john Vk2fah

How far is it from the deck to the window, and does the deck stick out past the utility bump out you mention?

If it's not far, have a friend stand on the deck with a broom, bristle end pointed at the window. Toss a light weight rope out the window over the end of the broom, and have the friend pull it in. Then use the rope to feed the coax over to the deck.

You also don't mention the siding. You might be able to use a nail or two, or find some existing protrusions like a gutter you can reach. Use those plastic clip ties to hold the cable down. (I can't remember the technical name, but you feed one end of the plastic tie through a little square hole at the other end of the tie, and it makes a little zip/click sound as it feeds through). These things are tough, but can be cut easily when it's time to move (and also make it easy to argue with the landlord that it's not a permanent installation).

Since it's the holiday season, you might also be able to get away with this: You said you are only on the second floor. Borrow a ladder from a friend. In the area where the coax is, hang up some sort of cheapy out door wreath (that's the excuse for being up there). While you are there, use plastic ties to secure the coax. After the holidays you can take it down and use the opportunity to run another piece or make adjustments.

in answer to an off-line post from the king of NG SPAM.

Charles- I dispute that you really have the need, or the right to SPAM
the news groups the way you do.
My Opinion, and, from what I hear, that of LOTS of others.

You claim it is "Necessary"- Why is it?, What is there about you that
makes you think you have more rights than others?

What makes you think this is polite behavior? Why should I go to a site
I think badly of to see your "FAQ's" ? I have been there before, and I
cannot conceive of anything that you have that will interest me.

My question was NOT if Bill knew of your site, it was if he knew the
risk he takes associating with SPAM.

Not trying to take sides here, but I am troubled with the accusation
of spam. USENET spam is defined as sending the same message to 20 or
more USENET groups. The message that started this thread went only to
rec.radio.amateur.antenna and does not fit the definition of spam.
Not even close. Or am I missing something here?

dick
i think the reason they are calling it spam is due to the person repeatidly
transmitting this same message every couple of weeks or so
when no one asks for it and its advertising a commerical website

Reg wrote:
"The Q of a transmission line is just the same as any tuned circuit."

True. F.E. Terman showed for the first time that the resonance curve of a transmission line used as a resonant circuit has the same shape as an L-C circuit with a coil and capacitor. Now, that shouldn`t be surprising, but in 1934 it was more newsworthy.

More often than not, we use a transmission line for what the name we call it by implies. When so used and matched to its load, a transmission line has broadband response. There is none of the circulating current associated with a tuned circuit in a matched transmission line.

See page 106 of Terman`s 1955 "Electronic and Radio Engineering" for "Transmission Lines as Resonant Circuits and as Circuit Elements"

Best regards, Richard Harrison, KB5WZI

1778. Re: W9INN Antennas - now ONLINE

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-12 02:32:08 UTC
From: Charles Johnston <ctj92@cableone.net>
Message-ID: <3bef34a5$1@news.bnb-lp.com>
Source record: 154930

Hello Dennis,
Let me clear a few things up....

1. My site is not a commercial site. I sell nothing from my web pages. As far as W9INN antennas go I simply post contact data and I do encourage people to contact W9INN to find out more. There are no order forms or the like anywhere on my site. It is impossible to buy anything (antennas or whatever) from my site.

2. I post the W9INN Page notice once a month on or about the 12th of each month.

3. The idea that I can only post what someone else likes is ludicrous. Anymore _any_ message some joker takes a dislike to for whatever reason is suddenly called SPAM. That is totally wrong....

4. Dick Hughes is right...my posts have nothing to do with the definition of SPAM. Just because you or some other fella does not care for me , my site, my posts or whatever does _NOT_ make me a bad guy and does not make a once-a-month message SPAM.

5. My posts fall well within the guidelines set forth by the news service I subscribe to. If you would like I can provide a link so you can educate yourself about what SPAM is and isn't .

Dick- you are missing a couple of things- for one thing- who made the "20 or more" definition?- for another- he sends the same crap over and over and over - etc, every month- and another- what makes you think he hits only this NG? I have seen this on mailing lists, in addition (today), and he probably has a long list. It is pure advertizing, and poorly done, at that.
By me- he is shooting SPAM. Your milage may differ.
Bill

THe government (FTC) defines this type of stuff as "UCE"- ie,
"unsolicited commercial e-mail."
THe repeated posts by Johnson are unsolicited, they suggest a visit to a
site that is designed to sell, therefore it is commercial, and by
appearing here and on other mailing lists (it does, you know), it is
e-mail.
By me- it IS UCE, therefore it is , colloquially, SPAM.
Bill

Don't know. You tell me. I don't know what the charter of this
newsgroup says about commercial advertising. But no, it does not fit
the description as it is generally understood. Spam is broadcasting
the same message to many newsgroups at the same time. It has been
likened to dropping a can of Spam into a fan. Goes everywhere. Fifty
manufacturers advertising at the same time would not be spam.
Individually, they may violate the newgroups charter, but it is not
spam. See http://spam.abuse.net/whatisspam.html for a better
understanding.

1786. "Actual" Radiated Power ???

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-12 04:53:26 UTC
From: cathexis@your.haterols.com
Message-ID: <3bef5284.869936062@news.erols.com>
Source record: 154939

Greetings,

After asking earlier about Relative Conductivity I will preface this by saying that I'm sure I'll probably miss a few relevant parameters in regards to my question(s). I'll be a technical as I can and hope plain language does the rest. Ask if confused.

In a nutshell,..... How much power is actually radiated from the antenna as RF ?

That is, assume your transmitter/transciever delivers x Watts to the feedline which then carries it to the antenna as well as any RG/8U can be expected to. How much is lost as "current" and how much is radiated RF ? Looked at another way, if my wattmeter says I'm putting out 500W with a perfect SWR of 1:1 and I then take that wattmeter and put it in series near the tip of the antenna --- would it still read 500W ??

Caveats: I'm not really trying to start a flame war on which antenna type is superior, but I realize that design came make a huge diff. here. Just assume an "ideal" if that helps you to answer. Assume SWR of 1:1 and that line losses are negligible (unlees you strongly feel they aren't). Hope this makes sense and you are inclined to reply.

TIA,

Andrew

No, I don't think I am missing anything. I have been on the Internet since before browsers and newsgroups even existed. If you don't like 20, then you pick the number. 5? 10? 100? 1000? Spam is broadcasting. That means sending the same message to multiple places "at the same time." Just because someone sends the same message over and over again on different dates, it is not spam. What makes me think he sent it only to this newsgroup is because I checked the headers in the message and it only went to this one group. Now I agree he could have sent verbatim individual messages to several newsgroups, but he did not cross-post which is usually an indication of the intent to spam.

The guy said he has no connection to the company, isn't selling anything, and doesn't derive any income from the notices, so how could it be pure advertising? I list information about products once in a while. I do it because I think others might want to know about it. It's not advertising, just information. I have monitored this newsgroup for a long time and I fail to see the harm. Maybe I am just more tolerant. I find it extremely easy and wise to not download messages whose headers don't trigger an interest. I would suggest that those who find his messages offensive, just don't download the message. Why read something that offends you? Seems pretty simple to me.

An awesome reply, Richard. Some other data that
I'm looking for would be comparisons in mmhos or
seimens of the relative conductivity of various common
salts. NaCl vs. KCl for instance. Got anything like that ?
Or ideas where to obtain these kind of figures ??

Andrew

The USENET and E-mail are two entirely different things Bill. Mailing
lists are comprised of people who have agreed to receive the mailings.
E-mail Spam is not the same thing. We have all received unsolicited
e-mail advertisements, and most of us can tell the difference between
a posting on USENET and e-mail Spam. I agree with the FTC definition
of e-mail Spam, but you are using it out of context.

Dick- he DID send the same message to the antennas mailing list- today.
that makes it (there) SPAM, by the UCE definition. I know he is using
separate postings, to stop the cross-posting accusations he has been hit
with in the past.
I had better stop- Nothing I say will stop this arrogant irritation.
Bye
Bill

Andrew- the loss in Coax transmition line is pretty well documented, and published. It is reported as dB/100 ft, and is in the handbooks, and on some vendors sites. However, the part of your post that said " assume--that line losses are negligable" is the hang-up. The losses are NOT negligable, and are one of the reasons some people like open wire line in preference to Coax.

Get a ladder and a bottle of Windex. If anyone asks why you're up
there, there was a big bird dropping on the outside of your window
that was really disgusting, and you didn't think maintenance would
care enough to clean it anytime soon.

Wipe the window while you're at it, in case they're watching.

...

If you go to groups.google.com and search for "5/8 wave antenna" and the like, you'll find lots of discussion and ideas archived (huge number of articles...the topic comes up all the time here). One reason you may not be finding what you want is that it's often done more generically: what sort of loading coil (or matching network) do you need for an antenna of more arbitrary length (and diameter)? Seems like one or more of Reg Edwards' programs might do the trick: ask him or poke around on his web site. Shamelessly stolen from one of his postings:
Free Radio Design Software.
http://www.g4fgq.com

You'll also see lots of discussion about the large ground plane needed for a 5/8 wave monopole to get decent performance. You might well do better with a half-wave dipole design. I gather you're looking for vertical polarization, but perhaps that's worth asking...Also, is it practical in your installation to center feed the antenna, or will it need to be end-fed?

Cheers,
Tom

Hi.

Yep, cable losses does exist.

Just want to draw Your attention to the fact, that even if Your
Watt-meter is attaced to the antenna itself, the radiated power
is NOT equal to the power fed into the antenna...

GUESS what compromize You're making when You put up one of these
nowdays quite popular shortened vertical "stealth" dipoles,
"no radials needed"??? Even the famous "dummy-load" G5RV is
better...

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3BEF932B.FD8A5589@eznec.com>
Source record: 154955

If you assume line loss is negligible, the amount of power radiated by the antenna is the amount produced by the transmitter minus the amount lost as heat in warming up the antenna conductors and, if there's a connection or near proximity to ground, to warming up the ground.

The fraction of the applied power which is radiated is called the antenna's efficiency.

A wire antenna which is a good fraction of a half wavelength long is generally nearly 100% efficient. That is, nearly all the applied power is radiated. Small antennas, and ones which try to get a whole lot of gain in a small space by strong mutual coupling, are often less efficient. Full-sized beams, quads, and dipoles are all essentially 100% efficient, so if you apply 100 watts to any of them, very nearly 100 watts gets radiated.

You can't measure the power at various points along the antenna and get meaningful results. Power is "sloshed around" in the near vicinity of the antenna, with some radiating to space each cycle. But if you measure it anywhere along the feedline, from the transmitter to the antenna, you'll read the same amount (again assuming the feedline loss is negligible).

The SWR has nothing to do with this. What I've said is true regardless of the SWR.

No power is "lost as 'current'". Current isn't power and power isn't current. The power you apply to an antenna is either converted to heat (we'd call that 'lost' when trying to radiate a signal) or radiated as RF. That's it.

Hey, don't knock it. "Monster" speaker cables do their intended job very
well. Which is, of course, not so much transferring audio from the
stereo to the speakers as transferring money from the suckers, ahem,
naive people to the con -- there I go again -- merchants. There are
quite a few antennas that are very effective in this sense, too.

I'll bet that the conductivities of these salts vary all over the map depending on moisture content. I know NaCl is highly hygroscopic, so its moisture content probably goes up and down with the relative humidity. If you're interested in the conductivities of solutions of these salts in various concentrations in water, you'll find them and nearly 100 others in the CRC Handbook of Chemistry and Physics. See "Concentrative Properties of Aqueous Solutions: Conversion Tables". The table even includes cat, guinea pig, human, and rabbit urine, but -- alas -- no conductivities for these.

Hi Reg,

I don't know about a written version of this story. I learned about it
when I visited a museum dealing with aircrafts located closely to the
ground of the hannover fair and from a few newspaper articles. The place
where it all happened is in the northern part of Hannover. If I remember
the numbers of the paper articles well, the "jump" was only 30 meters.
They said in the articles that Karl Jatho did not advertise his flight,
because he was employee of the prussian state and it was somehow forbidden
to him to try this kind of experiments. For this reason only very few
people witnessed this event and no photos were taken.
Maybe a search on the Web will lead to further results?

What kind of motor did the Wrights use ? Maybe a german Otto (the
grandfather of what most of us have in our cars nowadays ?--The others
have german Diesels or german Wankel engines ;-))

Cheers

> the best combination possible.
>
> Length of radiating element

587/freq in mhz = length

> Optimal Characteristic of the matching coil for given frequency.

Well, I dunno.. I guess use thick enough wire so it doesn't burn up.
The coils can be fairly small and self supporting. Most of mine are
about an inch dia and made with stiff 12 gauge wire. No form used, the
coils are self supporting as longs as the ends are clamped down. To
calculate the inductance needed you can use:

165/freq in mhz x 6.26 = microhenrys needed for insulated coil
305/freq in mhz x 6.26 = microhenrys needed for grounded coil

As an example a 10m 5/8 tuned to 28.5 would need a 20.596 ft whip.
The loading coil ungrounded would be 0.925 mh. Grounded coil would be

1.710 mh.
Go to here: http://www.g4fgq.com/ to get a solenoid.exe program to
convert the mh into coil dimensions.

> Diameter of coil.

Whatever you want to use. A large coil is not needed except on maybe a
low band antenna.

> height of coil.

Will vary with the dia and freq.

> Numbers of turns.

solenoid.exe will do all this..

> spacing between turns.

ditto...

> overall Length of coil with size of wire or tubing to be used.

Depends on the freq. Mine average 2-3 inches long, and inch or two dia
for 20-10 meters. Made with solid #14-#12 house wire. On 10m, might be
an inch or so dia with maybe 12-15 turns used.

> Approx distance from bottom to feed point.

Bottom of what?
>
> Variable input would be:
> Type of radiating element:
> wire (Portable use !) or Tubing single continuous diameter or Tapered
> type and Size of material for the coil (wire - small tubing)

Both will work. I prefer self supporting for the higher bands.
> I think i have covered most of it.
>
> This kind of information would certainly go a long way in improving the
> image of the 5/8th antennas
> I Understand that nothing is perfect and tuning would be necessary.
> But getting the theory right in the first place would definitely help.

They are simple to get going. Cut the element to length. Do not trim
it for a match!!! Adjust the coil to get the best match. If the SWR is
good low in freq, take off turns until it's tuned where you want it.
Resonant too high in freq, add turns. MK

I'll have to dig up some magnet wire. I think I'm going to make both
the preselector and a low pass filter. I'm trying to clean up the
lower part of that spectrum to try to hear the experimental stations.
The AM BC is killing me as is. The longwave reception on the 706 is
not one of it's stronger points. It's halfway usable in the aircraft
NDB section, but pretty lousy below 200 hz. MK

1806. UHF YAGI AS-2602/GR ?

I picked up a military UHF Yagi antena at a swapmeet.

It is tagged Antenna, UHF Yagi AS-2602/GR
SEC, INC CAT. NO HPY 625

Does anyone know its freq range or gain etc?

Thanks

George

Charlie, boy, do you get any kickbacks on orders you generate for w9inn?

Also, is w9inn aware of the hostility you generate every time you spam the newsgroups? I'm thinking of printing out all of the replies you've gotten to your latest spam, and sending them to w9inn. He might be shocked.

It's one thing to get a web page and advertise your product on the web. It's something else to spam the newsgroups with regularity.

You don't mention what kind of siding you have, but most hardware stores sell all kinds of little plastic and metal clips, to be used when stringing tv coax or phone wire throughout an installation, and they would work, as well, for 1/4" ham coax. Your nearest Radio Shack also has paraphernalia for installing coax. Just go have a look at your RS or neighborhood hardware outlet.

Even when using slingshot/arrow you might consider pulling a pulley up
for longterm antenna installation. Put a large loop of line throught the
pulley so the antenna can be raised and lowered, and of course a
weight can be used to maintain antenna tension while the pulley
provides low-friction. Use a good pulley so it will last.

Hi,

I want to install a HF vertical on my (flat building) roof and would like some counseil from you.

The main problem is that I can't install any radial, AT ALL. Just a not very high pole (or even a tower, but, again, without wind guys or radials). The building is 5 flat tall plus roof.

I have been looking at the Butternut HF-6V but that antenna seems definitely designed to be used with radials.

Another possibility is the Hy-Gain AF-640, wich is designed for this type of mount, but I don't know if the performance will be much lower.

As a last resort I have also been looking at the Diamond GP6 (of which I haven't seen much info in the group archives). This is the prefered one of the members in my club, but most of them have never had any other vertical, so I think their opinion is to be taken with care.

Another question is about grounding.

The question is that I can (with the oposition of all neighbours) run a wire from the antenna to a rod in the ground, or even from antenna to line entry in my flat and then to ground, but I don't think this may be a very good idea as it would make a second ground system isolated from the building ground. The building ground is completely inaccessible (apart from the ground contact at the wall mains sockets) and probably consists of the bare minimum rod required by law.

Please giveme your opinions on possible solutions to the antenna, ground or both questions.

Thanks in advance

Toni

Hi Andrew,
if your TRX delivers 500 watts into the feeder, the losses in the form of heat and of unwanted radiation of the feeder take place. Let's consider these losses to be 20 watts, so 480 watts reaches the antenna. You assume no reflection takes place (SWR=1:1), so part of this power is reflected and part is changed into heat - in the antenna itself !
What part ? The concept of "radiation resistance" describes that. Let's suppose your antenna has input impedance 50 ohms (purely resistive - no reflection), radiation resistance 10 ohms (always purely resistive), therefore the loss resistance is 50-10=40 ohms. The energy divides proportionally to the square of resistances, i.e. 1:16 ; so only 480 : 16 = 30 watts is radiated and 450 watts wars the antenna structure. :-(

Bill,

As I prefaced, I knew I'd miss one or several obvious points. Let me
try again in my best (but probably not so good) words to get my query
across in the least painful way. Please feel free to correct or enhance
if you feel it helps.

On average, if a rig is putting out say 500W to the transmission line,
how much makes it out as RF (not "current", transmitted RF that other
rigs might pick up as your signal.)??

Hope this helps,

Andrew

You might want to consider a half-wave vertical or one of
the magnetic loop antennas. They do not require radials. I
picked up a Cushcraft R7 at a flea market and am very
pleased with it. I also have an MFJ loop which I plan to
put in my attic. Neither antenna requires radials. The only
drawback is 80 and 160 meter coverage which must be dealt
with separately.

Tend to agree. Two resistances, loss and radiation, series connected, pass the same current. Ohm says voltage drop across each is proportional to its resistance. Power in each is E(I) or I squared R. Current is the same, so the power in each is proportional to R.

There is no loss in an antenna`s impedance transformation, if any, between radiation resistance and feedpoint resistance, any more than there is a loss in an impedance transformation in a transformer.

Best regards, Richarrd Harrison, KB5WZI

I have good experience with roof mounted Cushcraft R-5 and R-7 verticals,
neither of which require wire radials -- but they're not made anymore. You might
look at an R-8, R-6000 or MA-5V, all from Cushcraft. None require wire radials,
although they do have short, spindly metal rods protruding from the base.

Richard:

As you have noted, Terman and others who worked on transmission line filters noted that, near a specific "resonance", the impedance curve of a transmission line tank (An unterminated 1/4WL stub) closely matches that of a series tuned LCR circuit quite. So does that of a simple 1/2WL wire antenna!

But as one measures it at frequencies sufficiently different from resonance, esp on the high side, the impedance curve deviates significantly from that of a simple series RLC tank. A more accurate lumped approximation would be two or say three LCR tanks connected in parallel, the second tank resonant at 3/4WL, etc..

Actually a transmission line acts as a connection of many tuned circuits... an infinity of them to be precise.

But then you already knew that...

I doubt that. Do you remember "A news" and the transition to "B
news" then "C news" ? Then later the "great renaming" ?

newsgroups existed before the Internet was a connectable 'net.
Those days it was all UUCP (typically 300bps dialup) between even
the backbone hosts. IIRC usenet got started in the late 1970's...

> 20, then you pick the number. 5? 10? 100? 1000? Spam is
> broadcasting. That means sending the same message to multiple places

So if you post the same message 1 second apart it isn't spam?

Or if you change a word or two it isn't spam?

The idea is nonsense.

> Just because someone sends the same message over
> and over again on different dates, it is not spam. What makes me

Yes it is.

Your definition of spam might as well be provided by a spammer. Try
this for another definition: ''The term "spam," as used on this
newsgroup, means "the same article (or essentially the same article)
posted an unacceptably high number of times to one or more
newsgroups." CONTENT IS IRRELEVANT. 'Spam' doesn't mean "ads." It
doesn't mean "abuse."''
http://www.cybernothing.org/faqs/net-abuse-faq.html#2.1

> think he sent it only to this newsgroup is because I checked the
> headers in the message and it only went to this one group. Now I

That means it was not cross-posted. It does not mean it went only
to this group. It could (and has been) multi-posted. A multi-post
is even worse than a cross-post.

> newsgroups, but he did not cross-post which is usually an indication
> of the intent to spam.

Where do you get such stupid ideas?

> The guy said he has no connection to the company, isn't selling
> anything, and doesn't derive any income from the notices, so how could

So? That is irrelevent.

> that those who find his messages offensive, just don't download the
> message. Why read something that offends you? Seems pretty simple to

Because I've killfiled HIM a LONG time ago, but still these threads
crop up from people doing a followup to his posts.

As long as spam works EVEN IN THE SLIGHTEST people will keep
spamming. Any indication that people are paying attention to spam
indicates that spam is working. All spam is intolerable and must be
terminated. All spammers and their sympathisers must be taught.

1830. Elevated Feed Vertical Experiment

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-12 21:59:40 UTC
From: robert fanfant <robertfa@microsoft.com>
Message-ID: <3bf04669@news.microsoft.com>
Source record: 154882

GOAL:
I'm building an elevated vertical to be used on all bands 40 - 10 meters @ 100 Watts. The vertical portion of the wire antenna is 36 feet long with the bottom of the wire about 20 feet above ground. I have supports that can used to support 6 elevated radials at @ 20 feet high. I also have an SGC auto tuner that has a 50 ohm coax input, a single output lug and also a ground lug. I would elevate the auto-tuner at 20 feet and use the auto tuner output to tune the vertical portion of the antenna with the radials connected to the auto-tuner ground lug.

Question #1:
Does it make sense to bundle multiple lengths of insulated wire for each of my radials? Each wire in the bundle would be cut to the quarter wave length for a band of interest(i.e. each radial would consist of a wire for 40m, another for 30m,etc...? Or should I just have put up 6 radials with each radial being 36 feet long?

Question #2:
Should I have isolator/choke at the input to the auto-tuner to prevent currents flowing down the outside of the coax to my rig?

Question #3:
Another possible configuration is to use a balun. I would connect the vertical wire to one lug of a balun and the radials to the other lug of the balun. I would then connect the output of the auto-tuner directly to the input of the balun. Would this antenna work any better?

-rob N7QT

>http://www.g4fgq.com
got them all..Still some discrepancies..

>Also, is it practical in your installation to center feed the antenna, or will it
>need to be end-fed?
Well.. would be easier to have it bottom fed..
(Tower interaction) but i'm willing to consider center feed
in true Zepp spirit.
I saw that site about the double Zepp for 2 meters using nylon cutting
board insulator and find it interesting:
http://hem.passagen.se/sm0vpo/antennas/6dbvhf0.htm

another one apart from the terrible background graphics (better download
and edit the background out)it is this one:
http://www.geocities.com/Paris/Metro/9773/gerigai.html
As a matter of fact i have a gazillion design here saved from the net.

Still no specific prg or set of equation to make the "perfect match"
according to frequency.

Maybe it's just an excuse not to start one! ;-)
But i like things tidy and accurate.

Gentlemen, I suggest that you both look up "Breidbart index" on
some search engine -- say, Google or Altavista or AskJeeves. You
will find the accepted definition of how to determine whether a
particular Usenet posting is spam. It is in use world-wide.

Until then, neither of you has the rules in hand from which to
make any sort of argument.

I managed the abuse desk for a Tier-One Internet bandwidth
provider out on the Left Coast, and was "privileged" to get to
deal with UCE as well as with Usenet spam. I found it rather
more educational than I wanted it to be, and was able to get
the corporate AUP amended to include Seth Breidbart's definition
of Usenet spam.

>John, download program BOTLOAD in a few seconds from website below.
>Not zipped up. Run immediately. Just written for you !

I actually did the other day ..And downloaded all your prg in one hit..
Thanks a bunch.
As for bootload I have a few questions:
1) what ratio are you using for the calculation of the radiating element as
if you input 100 mhz and a length of 3 m(For Test purpose)
you end up with a full theoretical wavelength.

Now even when using wire the velocity factor play a role
secondly the speed of light is not exactly 300 000 kms
Finally. Varying the size of the radiating element and the length of wire
in the coil seems not to affect the length of the antenna.
so not sure there !!!.

2) you asked for length of coil..
Good question ! How should I know before i have the answer tho the
necessary inductance!
3) Winding pitch ..Same as above !
also confusing .. Wouldn't it be easier if one just had the number of turn
evenly spaced on the coil former.
otherwise what's the point of asking coil length!
As you can see I still have a few unanswered question..
Don't get me wrong i'm not putting you down..
and still can see the work you must have put in these prgs of yours.
Just trying to make it easier that's all.\
All the best.

Well sure, lets go back to 1957 and the formation of ARPA. I'm obviously talking about USENET as we know it today, which came into being about the same time as the Mosaic browser. Unless you were connected with a university or the military, the Internet was not readily accessible to the average person until the early 90's.

I did a little checking on this person's posts. On November 11th, he posted a message to three newsgroups with the title of, "W9IIN Antennas - now ONLINE" or words close to that. The last postings of the same type were on August 11th, about 60 days prior. I submit that anyone who thinks that the posting of 4 words on 3 newgroups 2 months apart is some kind of horrendous spammer that will ruin your life and cause birth defects in your children or other, equally horrible results is totally paranoid and shouldn't even be reading these newsgroups. Try some of the alt. newsgroups if you want to read things that will ruin your day.

You claim to understand the meaning of Spam, but you don't seem to have a clue.

All of the fighting we are doing over the definition of Spam on an amateur radio newsgroup, which has NOTHING to do with antennas, is FAR worse than any Spam that might be present. Color me gone from this thread.

Add a bit of coil loss. It would be better to just go in a different
direction with the wire if possible. I do this on 160m using a "Z"
dipole. I go out about 70 ft from the apex, and then double back to
make a Z. I compared with 2 versions of coil loaded dipoles, and the Z
is quite a bit better. MK

1840. Antenna Static Follow Up

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-12 23:29:43 UTC
From: Murray Green <mgreen@erols.com>
Message-ID: <3BF06977.76D34E34@erols.com>
Source record: 154893

1.) About a month ago I posted a message that discussed antenna static on a Cell Wave commercial vertical dipole antenna for 2 meters, mounted in the center and just above the center top of a cone shaped water tank. The static occurred only on windy days and could be heard on weak to moderate incoming signals to the Club repeater.

2.) On Saturday, November 10th, the tank was climbed, the antenna removed and laid down on top of the tank. A thorough inspection of the "trombone" dipole elements and their connections to it's support mast showed no signs of deterioration, or loose connections. All four elements were very solid. (Photographs were taken for future reference and discussions with the Company.)

3.) Some continuity checks were also made however the phasing harness is located inside of its tubular mast and is totally inaccessible. So if there were any loose connection inside it could not be determined. The bracket mount that supported the antenna was thoroughly cleaned of paint and sanded to a shine along with associated parts. (Note: The tank was painted about 2-3 years after the antenna was installed and about the time the static began. We thought for certain that was the problem.) Additionally an extra ground wire was installed although the antenna is DC grounded. The antenna was then remounted.

4.) The wind picked up just about that time and while the static was reduced it was not eliminated. Discussions will be held with Cell Wave representatives although previous discussions provided nothing concrete.

5.) What is frustrating is that we could produce the static by shaking the antenna mast which sort of points to the harness since the elements were absolutely tight. But not having access to the inside of the mast where the harness is located makes it impossible to confirm.

6.) Just an update since we received some excellent replies to the problem. Something has to have deteriorated because for the first 3 years of operation, there was no static problem. Ironically, an identical antenna on a sister repeater located about 10 miles away has no problems. In this case, the antenna is mounted to the side of a water tank. Both antennas were installed around the same date; perhaps a month apart.

Thats the route I would take. Some kind of 1/2 wave design. Trying to
use a 1/4 wl design vertical without radials will be a disaster. Not
only poor performance, but interference and common mode problems
galore being as the feedline will be part of the antenna. MK

> particular Usenet posting is spam. It is in use world-wide.

No you won't. The BI definition does not define spam:

''The Breidbart Index (BI) is a measure of the breadth of any
multi-posting, cross-posting, or combination of the two. BI is
defined as the sum of the square roots of how many newsgroups each
article was posted to. If that number approaches 20, then the posts
will probably be cancelled by somebody.''

Sometimes the BI is used as a criteria to determine if a message is
spam, sometimes not. It is certainly not the be-all and end-all of
the defintion of spam.

The SWR is meaningless--the true SWR at the antenna could be caused by high losses in the coax cable, which act like a resistive pad in line. Conversely, most of your power could make it to the antenna despite a high SWR reading if you are using a low-loss transmission line.

> transmission line tank (An unterminated 1/4WL stub)
> closely matches that of a series tuned LCR circuit.
==========

- - - and the input impedance of a short-circuited transmission
line closely matches that of a parallel tuned LCR circuit.

Terman was by no means amongst the first to point out this rather
obvious (at least to engineers) fact. Heaviside around 18
(eighteen) 75 was already very well acquainted with the notion.
Kelvin, 100 years before Terman, must have been toying with the
idea.

But we had to wait till 2001 for Edwards to announce that -

Q = 1.29*(Ln(lambda/2/d) - 1)

Tee hee hee.

You utilized a definition of SPAM as something strictly relating to email.
This is not email- this is Usenet. Therefore, the comparison, in the scope
of your definition, was invalid.

Condescending? It may have seemed that way, but was not meant that way.

FWIW: I still mostly agree with you- it was Spam, but the definition you
used did not support your argument.

Jeff,
It will work. It'll be fairly 'narrow' banded, and touchy to tune, but
it ~will~ work. As suggested, a different 'shape' to a doublet with no
coils in it might work 'better'. But, you have to 'do' with what you have
to 'do with...

Harley,
That's a very 'broad' question that depends a lot on where you plan to use the antenna, how it's mounted, the heigth you can 'put up' with, and personal preferences. There's no 'one' correct answer.
In general, most of the mobile antennas you find now-a-days are about the same 'electrically', only different in 'looks' and how much you pay for them. If you install and tune the antenna correctly, any of the commonly found antennas should work okay. Also in general, the shorter the antenna the worse the signal (sort of).
This doesn't answer your question directly but it should help a little bit.

I am putting up a tuned doublet this weekend. It will be supported, at 45' atop a guyed 20' galvanized steel mast, 1.5" diameter, mounted to my chimney. I am feeding the antenna with 1" 18 ga. ladder line, and am concerned that the line, and especially the center connector (one of those "ladder-grabber" devices) will contact the mast, or just come too near it, and cause tuning and other problems. I need ideas how I can mechanically insure that the center connector does not come in direct contact with the metal mast, and how best to secure and route the line away from the feedpoint (it needs to drop 25', cross 10-12' of roof, then down another 7' and in the wood window (luckily the house is almost metal free in construction) to my HB link-coupled tuner.

AMATEUR RADIO NEWSLINE(tm) REPORT #1265 – NOV. 9, 2001

Amateur Radio Newsline report number 1265 with a release date of Friday, November 9th, 2001 to follow in 5-4-3-2-1.

The following is a Q-S-T.

Ham radio leads the way at the New York City Marathon. This story is first on Amateur Radio Newsline report number 1265 coming your way right now.

(Billboard Cart Here)

**

HAM RADIO AND SPORTS: - THE NEW YORK CITY MARATHON

Ham radio was once again at the start and finish -- and all along the route of this years 32nd running of the New York City Marathon. This years event was held Sunday November 4th and was dedicated to victims of September 11th terrorist attacks. Its theme -- “United We Run.”

The starting line was at the Staten Island Side of the Verrazano Narrows Bridge. According to Stew Seit, WA2JNF, who was assigned there, it was a moment of total patriotism:

--

WA2JNF: “On the bridge waiting for the cannon to go off, everyone began singing patriotic songs. It would brng a tear to your eye. There were 30,000 people singing. It was something to be seen.”
--

But Seit and almost 500 other hams were there to provide communications for the event. And according to WA2JNF, even though there were lots of cellular phones, it was ham radio that was the communications backbone once again:

--
WA2JNF: “Everyone was running around with digital radios, Nextel’s, cellular phones. But when the need came to get the message through they turned to us hams. Regardless of how many cell-phones or trunked radios they have tied around their necks, when the message was of priority nature, and they wanted to make sure it got through, they spoke to one of the hams who was handling the communications and we got the message through”
--

The crowd lining the route was estimated at more than two million. Many were waving small American flags in memory of the thousands killed in the terrorist attacks.

ARRL Hudson Division Vice Director Steve Mendelsohn, W2ML, heads up the the ham radio communications for the Marathon. In fact, he has been organizing the ham radio effort ever since Amateur Radio became a part of the event many years ago. He says that for him, for the group of Amateur Radio volunteer communicators and for the people of the Big Apple, this years New York City Marathon was like none ever before:

--
W2ML: ”It was truly a celebration of life. It was a way of saying to the terrorists: ‘look -- we are going on with our lives. You didn’t stop us. On the contrary, you united us.’ “
--

Tesfaye Jifar of Ethiopia set a record in winning the mens catagory. He ran the 26.2 mile course in 2 hours, 7 minutes, 43 seconds. The old record of 2 hours, 8 minutes and 1 second was set in 1989. And as Jifar broke the record it was a corps of ham radio operators that guided him -- and the 30,000 other competitors in the New York City Marathon -- to a safe completion of this years run.

More on the Marathon is on the web at www.nyrrc.org. Our complete interview with Steve Mendelsohn W2ML can be downloaded from our FTP page by clicking on the newscast number at the top of the www.arnewsline.org home page. (ARNewsline(tm))

**

RADIO AND SPORTS: THE SANTA CLARITA MARATHON

Sunday November 4th also saw another Marathon where ham radio played an important role. This one took place in Amateur Radio Newslines’s own back yard. It was the Santa Clarita 5 K Marathon and featured ham radio as it primary communications. Take a listen:

--

About three dozen hams from the Los Angeles County Disaster Communications Service and the Santa Clarita Valley Amateur Radio Club provided this years communications support. Most of it was on two meter F-M using the 146.79 MHz W6JW club repeater.

--
Audio here
--

The Santa Clarita Marathon may take place in a Los Angeles suburb, but it is by no means a small event. Several thousand runners take part and its course is USA Track and Field certified. In fact, this event is a qualifying race for the famed Boston Marathon.

More information on the event is at www.scmarathon.org. The Santa Clarita Amateur Radio club’s home in cyberspace is www.w6jw.org. (ARNewsline(tm))

TECHNOLOGY AND RADIO RULES: FCC PUTS KENWOOD "SKY COMMAND" PETITION ON PUBLIC NOTICE

Turning to regulatory matters, the FCC has put a rulemaking petition from Kenwood Communications Corporation requesting that the government relax restrictions on Amateur Radio auxiliary station operation on public notice. Amateur Radio Newsline’s Bruce Tennant K6PZW has the details:

--
The FCC assigned the rulemaking number RM-10313 to the petition in which Kenwood asks the government to permit hams to use control methods like its own Sky Command radio remote system.

According to the ARRL Letter, Kenwood’s Sky Command lets a user control a fixed location High Frequency station using a pair of dual-band VHf/UHF transceivers on frequencies in the 70-cm and 2 meter bands. Kenwood wants a change in Part 97 rules that would expand permission to operate an auxiliary station on all 2-meter frequencies above 144.5 Mhz, except on 145.8 to 146.0 MHz.

And while not mentioning Sky Command by name, Kenwood says that the proposed rule change would allow the development and use by amateurs of new technology devices and increase the utility of the limited amateur allocations. Current FCC rules limit auxiliary operation to certain frequencies above 222.15 MHz.

In July 2000, the FCC declared that use of the Sky Command did not comply with Amateur Service rules--specifically Section 97.201(b). It also declined to grant a waiver make it legal. The ARRL commented in opposition to Kenwood's earlier efforts to have the system eclared to be in compliance, and it refused to permit Sky Command advertisements to be published in its QST magazine.

In its Petition for Rule Making, Kenwood asserts that auxiliary operation is poorly defined and significantly overregulated in the FCC rules. Kenwood also argues that present limitations on auxiliary operation no longer are appropriate in today's amateur environment and should be withdrawn.

For the Amateur Radio Newsline, I’m Bruce Tennant, K6PZW.

--

Again, the Commission has assigned the rulemaking number RM-10313 to the petition from Kenwood. Those interested may view and comment on it via the FCC's Electronic Comment Filing System. (ARRL)

TECHNOLOGY AND RADIO RULES: DIGITAL WIRELINE REMOTE BASE OPERATION BEING TRIED IN THE UK

A British ham radio operator has been granted permission to experiment with a digital wireline multi-band remote-base system. The experimental station was made possible by combining a popular H-F transceiver, the support of the national ham radio society and a cooperative government regulatory agency. Jeramy Boot, G4NJH, reports from Nottingham in the U-K:

--

Dave Gould, G3UEG, has received a Notice of Variation as a Special Research Permit to set up an HF station that is remotely controlled over the telephone network. This has come after 16 months effort liaising with the RSGB Licensing Advisory Committee and the Radiocommunications Agency and has been finally approved after a site inspection. The system is based on a Kachina 505DSP transceiver and Kachina's own specially-designed remote control system. The audio is digitised and then multiplexed with the control signals. The resulting single data stream is encoded and then passed over the telephone network using standard modems. At the remote end the data is decoded and the audio is split from the control signals and passed to the transceiver. The system will operate at a line speed of 28K or better and includes strong security, failsafe and shut-down measures.

Jeramy Boot, G4NJH
--

While we in North America take wireline and radio remote-base operations for granted its new to many other parts of the world. Anyone interested in receiving further information or with ideas to assist Dave Gould, G3UEG, may contact him by e-mail at david.gould@btinternet.com (RSGB)

ATTACK ON AMERICA: COMANDO SOLO DOES NOT WANT RECEPTION REPORTS NOW

If you are an SWL or ham who listens to shortwave -- and -- if you are planning to send a confirmation card to Radio Solo, the word right now is -- dont! This as the United States forces 193rd Special Operations Wing asks that reception reports and cassette tapes of its Commando Solo flying radio station broadcasts over Afghanistan not mailed to them at this time.

According to the Media Network e-newsletter there are two reasons. Obviously, they are involved in operations over a theater of war and need to lessen their peripheral workload. Also, due to the Anthrax scare in the United States, the U.S. mail system is overloaded with new safety procedures. In other words, your report may be indefinitely delayed or never opened. (Media Network E-Newsletter)

**

ATTACK ON AMERICA: NYC TELEVISION SEEKS NEW HOME

Seven weeks after a terrorist attack caused the collapse of the World Trade Center, hundreds of thousands of homes in the New York City area remain unable to receive more than four television stations. Because the main antennas atop the north tower came down, all the local stations, except Channels 2 and 41, which had backup antennas on the Empire State Building, had lost a significant part of their audiences. The situation improved last week when two more of the stations that lost their main transmitters began broadcasting from the Empire State Building site. Amateur Radio Newsline's Henry Feinberg has more:

--
On Thursday morninng, October 31st, Tribune-owned WPIX-TV channel 11 switched on a transmitter giving it an over-the-air signal said to be similar to what it was prior to the terrorist attacks. WNBC-TV channel 4 -- which in the late 1940's was the first to broadcast from the Empire site -- made a triumphant return later the same day when it flipped the switch on its new Empire located transmitter.

As an interim step to get back on the air, most local broadcasters had opted to use the old Armstrong Tower located in Alpine New Jersey. But the Alpine tower is not high enough and is to far away from the majority of the New York City demographic audience to provide clear reception throughout the metropolitan region.

The Empire State Building was the home to almost all New York City television broadcasters before the World Trade Center was built. Many broadcasters want to return to it but the New York Times says that Empire has to little space and not enough electrical power to accommodate the demands of all the stations. So a coalition of 11 broadcasters in and around New York are exploring options that include sharing management of a broadcast tower built to their specifications and needs.

The Times says that the long-term situation may be the construction of an enormous stand-alone broadcast tower. One that is perhaps 2,000 feet high and preferably be somewhere near the World Trade Center twin towers site.

But broadcasters will face a large number of issues if they persue the stand alone tower idea. Chief among them are the wants and desires of the residents of New York City. Many of them have made it clear that the area where the twin towers once stood be rebuilt a both a new trade center and also as a lasting monument to those who died in the terrorist attacks of September 11th, 2001.

Not far from the Armostrong Tower in Alpine New Jersey, I'm Henry Feinberg, K2SSQ, reporting for the Amateur Radio Newsline.

--

Aside from the political issues mentioned in Henry's report there will be numerous other technical roadblocks. First is that of protecting the Philadelphia and Boston demographic television markets from interference. And if such a project is approved by the city at a different location, the Federal Aviation Administration will likely demand that it be built where it will avoid established flight patterns for local airports. And there are not very many of those in and around the metro New York City area. (ARNewsline(tm) from various published news reports.)

**

ATTACK ON AMERICA: VERTEX STANDARD / YAESU DONATES GEAR

According to a recent story in the ARRL Letter, Vertex Standard, which manufacturers Yaesu brand gear, has donated several pieces of equipment to Virginia ARES. The manufacturer had arranged to loan an FT-7100 transceiver and three of it's VX-5 hand-held's during the response to assist the Salvation Army at the Pentagon terrorist attack site. When the work concluded, Virginia Section Emergency Coordinator Tom Gregory, N4NW, e-mailed to thank the company and to inquire about returning the equipment. Vertex Standard Executive Vice President Mikio Maruya, WA6F told him that Virginia ARES was welcome to keep it on hand for future emergencies. The Woodbridge, Virginia, Ham Radio Outlet store cooperated in providing the Virginia ARES team with the needed equipment on September 13th. (ARRL)

REPEATER COORDINATION NEWS: NFCB AND NFCC ELECTION RESULTS

The National Frequency Coordination Council -- or NFCC -- has elected Nels Harvey, WA9JOB as its new President. Harvey replaces Owen Wormser, K6LEW. Wormser had served as Chairman of the original drafting group that resulted in creation of the NFCC back in mid 1990's and as several terms as President.

Also elected to office are Dave Baughn, K4XI as NFCC Vice President, Dick Isely, W9GIG as Secretary and Clay Freinwald, K7CR as the organizations Treasurer. Meantime, Clay Freinwald, K7CR, and Nels Harvey, WA9JOB, have also been elected for two year terms on the National Frequency Coordinators' Board of Directors. Both ran unopposed. (ARNewsline(tm))

**

REPEATER COORDINATION NEWS: SERA DROPS UNKNOWN CATEGORY

The South Eastern Repeater Association says that it has dropped use of the term 'unknown' for listing repeaters that it has little or no information on. According to the organizations publication Repeater Journal, the listing of about 150 repeaters as 'unknown' was intended to prod their owners to file delinquent updates or help clear the groups records of repeaters that are no longer on the air.

It did neither, but it did cause confusion for ham radio enforcement efforts. This occurred earlier this year when FCC Special Counsel Riley Hollingsworth cited the South Eastern Repeater Association's Unknown Repeater List as grounds for dismissing a complaint against an uncoordinated West Virginia repeater that had been accused of interfering with a coordinated system in Kentucky. The coordination counsel's FCC Liaison is reportedly working with Hollingsworth's office to clear up the confusion. (SERA Repeater Journal)

**

HANDI-HAMS: WINTER RADIO CAMP IN MALIBU IN MARCH 2002

The next Handiham Radio Camp session will take place the first week of March, 2002, at Camp Joan Mier in Malibu, California. That camp will be offering classes in Technician, General, Extra, Operating Skills, and JAWS computing.

There is no tuition charge for West Coast or D-X members aside from the $45 registration and insurance fee. If you want to receive a camp application packet, please e-mail handiham@courage.org or call 1-866-426-3442 -- days -- Central Standard Time. The most current camp information is available on the Handiham website located in cyberspace at www.mtn.org/handiham. (Handihams)

INTERNATIONAL – BAHAMAS: FEES GOING UP

The annual fee for those holding a Bahamian Amateur Radio license has increased to $25. According to the ARRL news, The new fee applies for licenses renewed after August 1. The cost to "catch up" on past renewal fees prior to 2002 is $6 per year. Some US amateurs with Bahamian tickets were surprised to get letters requesting the back renewal fees and threatening fines and revocation. According to Dick Long, C6AKE, the Bahamian Public Utilities Commission--which handles licensing there--collects $6 a year for the years your license has been expired--this has always been its policy, he says. If you don't plan to use your license anytime soon, Long advises returning it to the P-U-C or sending a letter stating that you won't be using it again. "If, at some future time, you want to return to the Bahamas, you can always apply for a new license," he added. The P-U-C e-mail address is puc@batelnet.bs. (ARRL)

**

INTERNATIONAL - BELGIUM: A BLESSED EVENT

Hams in Belgium are getting to take part in a truly blessed event. This, as John Devoldere ON4UN who is the President of the Belgian national Amateur Radio society announces that nations radio amateurs can use the special prefix OQ instead of their usual ON or OT prefixes.

According to Devoldere, Belgian telecom authorities issued this special prefix on the occasion of the birth of Princess Elisabeth. The permission to use the OQ prefix began on October 26th, runs until December 31st. (RSGB)

**

INTERNATIONAL - NEW ZEALAND: THE NATIONS HAM-STATS

The New Zealand Ministry of Economic Development reports that as of November 1st that nation has 3,295 General Class license holders, 1717 Limited license class, 24 Limited Novice and 25 Novice class operators. These hams share 205 voice repeaters, 19 television repeaters, 29 digipeters, and 42 beacon operations. Mix in two fixed licenses and the grand total is 5358 licenses issued. (NZART)

HAM RADIO IN SPACE: ISS TALKS TO NEW YORK CITY SCHOOL

Ten elementary school students from New York City had some very specific questions about current events for International Space Station Commander Frank Culbertson. To the question, "What did it look like in New York on September 11," Culbertson responded that he could see the smoke rising from the World Trade Center site and drifting south.

--
Culbertson: “On September 11th we happened to be coming over a few hours after the attack and I could see a large column of smoke coming out of the World Trade Center and floating off to the South and a kind of a fog of smoke all over the Southern part of the city.”
--

Culbertson went on to explain that he took pictures of the tragedy from space. He further related that he found out about the event while talking to his doctor during a scheduled medical conference.

Another youngster wanted to know, "What does Afghanistan look like from space?" Culbertson answered that it appeared to be very desolate and rugged.

The questions could be expected. The children are students at P.S. 234, with its regular campus only two blocks from the site of the World Trade Center.

On September 11, all 650 students at the school and their teachers evacuated their building without a single casualty. The school community has stayed together despite the turmoil, and is now housed in temporary quarters elsewhere in Manhattan. Culbertson told the students that he admired them for their courage, and told them to continue to study.

--
Culbertson: “ I want you to know that the whole world is very proud of you. Its to bad that you had to move from school to school, but we are very proud that you are continuing to work and take your education seriously. Things will be alright. Don’t worry.”
--

The students asked a total of twenty questions during the ten-minute contact. Some thirty teachers and parents and reporters were also on hand as were reporters from the New York Post and New York Daily News newspapers.

The ham radio contact was made through the Amateur Radio on the International Space Station project, an international coalition and was carried live by MSNBC on its website. Former NBC science editor and Newsline anchorman Roy Neal, K6DUE, moderated the event. Communication was handled through W6SRJ, a club station at Santa Rosa Community College in California, with Herb Sullivan at the controls.

P.S. 234 has its own website. Its in cyberspace at www.ps234.org/about.html (ARISS via K5YFL)

**

HAM RADIO IN SPACE: AMSAT-OSCAR 40 UPDATE

AMSAT's Peter Guezlow, DB2OS, reports magnetorquing of the OSCAR 40 ham radio satellite is again in progress. Guezlow also says that operational periods for the RUDAK system have been extended recently. This, to allow downloading of several important RUDAK G-P-S files.

AO-40 is currently in a long period during which the Earth eclipses the sun near the satellite's perigee. This actually began about August 28th, and will rapidly increase in length. The eclipses will continue well into June 2002. (AMSAT-NA)

**

SPACE AND SCIENCE: A LOT OF BIRDS UP THERE

SpaceDaily reports a new survey by the Teal Group has identified some 600 active satellites in Earth orbit or in deep space. The survey factored in all satellites launched since 1980, and, after a process of elimination, arrived at an estimate of 600 to 610 for satellites that remain active today. (AMSAT-NA)

**

DX

In D-X, you may recall that shortly after the September 11th terrorist attacks on New York City and the Pentagon, the government of Kuwait permitted its ham radio operators to the call sign 9K2USA. Now Bob Furzer, 9K2ZZ, reports a very positive response to the use of 9K2USA.

9K2USA was used by all Kuwaiti hams through September 30th as a token of the sympathy and support for the people of the United States from the citizens of Kuwait. It was also meant to be a statement of deep condolence.

Furzer now tells the Ohio Penn D-X Newsletter that the Kuwait Amateur Radio Society wants to thank all of those radio amateurs who e-mailed their support of the use of this special call. 9K2ZZ also says that the design of an official commemorative 9K2USA Q-S-L card has been finalized and is now posted on the website at www.k4cy.com. (OPDX)

From the U-K comes word of a new microwave D-X record. At least a new record for that nation. On Sunday October 21st the UK distance record for the 47 GHz band was raised from 163 to 203 kilometres. This happened when G7MRF and G0HNW, from Cambret Hill in grid I-O-74 had a two-way CW contact with G0IVA in gridsquare I-O-73 in North Wales. This distance comfortably exceeds the former record of 161 kilometres set in September 1999 by the same group. Reports of RST 519 and 419 were exchanged. (RSGB)

**

THAT FINAL ITEM: A MESSAGE TO REPEATER OWNERS FROM THE FCC

And finally this week, a word about repeater communications responsibility. It comes from the FCC's chief ham radio rules enforcer Riley Hollingsworth, and was included in a recent RAIN Enforcement Log Question and Answer session. If you own and operate a repeater, the next few minutes will be very important to you:

--

First of all, no licensee is required by the [FCC] rules to set up a repeater. When you do so, you do have certain responsibilities.

First, assuming that you have applied for and received coordination from your local repeater coordinating body -- if there is one -- and in a lot of areas there are not and in which case you would skip that step. As long as you are not interfering with a coordinated repeater, everything is all-right.

Once you start a repeater, you have to keep a few things in mind. First of all, if it is using your call sign -- it is your station -- and you are responsible for it. You do have a few alternatives as far as controlling it, but essentially it is your station and your responsibility.

The rule that states that you are not responsible for inadvertent transmissions I am afraid is often misunderstood. It only applies to inadvertent transmissions. [These are] transmissions that you let through on the repeater -- and I think it was designed for [modes like] packet anyway that you let through on the repeater before you realized what was happening.

Now, rules violations that occur by your users on a day-in and day-out basis or rule violations that go on for several hours are your responsibility as well as that of the users that are committing the violations. No dictionary in the world would define those types of situations as "inadvertent," and I am afraid that a lot of people just do not understand that.

If you put a repeater on [the air] you are responsible for its proper operation. Now, if you can't do that, or you do not have the time or the inclination [to properly control it], then your choice is to shut if off and to do something else. This is very important in these times because Amateurs are being listened to more than ever before.

Everyone seems to be buying scanners and short-wave radios. Very often a repeater is new person's first exposure to Amateur Radio -- and a potential recruit -- I might add. And, very often, it is the news media's first exposure to Amateur Radio.

If your repeater is an embarrassment to Amateur Radio, then you should shut it down and seriously examine your motives for wanting a repeater. You will be held responsible for regularly occurring rules violations, as well as the people committing the violations.

I would hope that more and more Amateurs would understand this. I think that the rule that you are not responsible for inadvertent transmissions has been misinterpreted by a number of people.

--

What Hollingsworth really seems to be saying is that your repeater is kind of like your house and your surrounding property. Yes, you have responsibility to make your home secure for you and your family. You also have a responsibility to keep it and its surroundings neat and clean so that your neighbors will also enjoy the view. (FCC, RAIN)

I've seen some references here to using a slingshot to raise a dipole. Presumably, you shoot some kind of a projectile up into a tree, with a leader line attached, and hope it loops over a branch that's high enough, and further hope that it then falls down low enough to reach.

What is the real procedure for doing this?

For those of you who have done it successfully, how high have you been able to get your antenna?

Where can I buy a slingshot that's suitable for this, and what kind of projectile and lead line should I use?

Thanks...

Any wrist rocket that uses surgical tubing works well. I use a zebco 202 fishing reel with 10# test and a 1oz bell weight. Ive gotten mine as high as 70-80 feet CAUTION CAUTION CAUTION going that height you MUST find clear enough behind it else you may be far into your neighbors abode and possibly windows.

What I do is aim above my target as you need to allow for droppage, once you get it over I pull it back till its now dangling verticaly then let it drop down through the tree (Multiple pulling up and dropping to get past them nasty points) when the weight reaches the bottom I then remove the weight and tie a small sized nylon rope to it and reel it back till the rope reaches me.

Then I tie the larger rope I need and pull it back (tape over the ties to make it through tight spots) once I reach the end then I tie a Pulley with a nylon rope ran through it and carefully pull it into place. Work from there.

I have used a wrist rocket to shoot lines OUT of a tree that I climbed.

I have also used a pneumatic Canon to pull lines into a tree. I took a sock
and put a few ounces of sand in it, then tied a rope to the sock. Put it
down the barrell of
a 2" air cannon, and used 80 psi to launch. Although the sock can come down
hard, it seem much less damaging then fishing wieghts.

SOME towns consider this king size pea shooter to be a gun. Don't fire it
at a window!

You used to be able to buy stand-off holders for TV twin lead. I
think they may still be available---not sure---but they might be too
small for your 1" line. There are some available for holding TV coax,
too.

You certaintly want to keep the ladder line several inches away from
all objects, metal or non-metal. Perhaps you can go to a place that
sells TV antennas and cable, and get some of the stand-offs. Use them
to hold just one side of the ladderline if it is too small to hold the
whole thing.

USA got the best of that trade! Location and ranging would not have been the same without radar, magnetrons, and loran.

Development of klystrons might not have come soon enough for success in WW-2.

Stanford University and the University of California have now collaborated to develop multi-megawatt pulsed klystrons for 2 to 12 GHz. They have also developed CW klystrons for megawatt levels in the UHF band.

I purchased a slingshot at K-Mart (in their gun department), some fishing line and some fishing line lead weights for this purpose and it works well. It does take a few tries to get it right where you want it. I have mine up about 50 feet.

The directions for using the Zebco reel are right on. I just did the exact same thing (except the reel was a 404) the other day and it really works. Got the line up nearly 100 feet to the top of a pine tree on the first try.

The wrist rocket costs $5 and the reel $10. The 2 small hose clamps to attach the reel to the slingshot were about 50 cents each. I've seen commercially made outfits like this sell for as much as $80!

> according to frequency.

So...I think you're asking too much. First of all, don't be so hung up on the "perfect match." Then be willing to get in there and do a bit of tweaking, assuming you have some basic test equipment to see what the match looks like. It's a really safe bet that the feedpoint impedance will depend not only on the radiator but also on the rest of the environment the antenna is in...especially the counterpoise against which it is fed. If you design it for nominally the conditions you have, but have the ability to tweak on it, you can get it as "perfect" as you wish, or at least as "perfect" as your test equipment allows.

If you want to play with models, you might also have a look at www.eznec.com for a free demo version that will let you get a feel for the effects of changing various parameters. You can use any of the various "Smith chart" matching programs or just put it in a spreadsheet to see what sort of coil/capacitor might be appropriate for matching the feedpoint impedance of the antenna to your transmission line. ("L" matching networks are generally straightforward to implement, especially when you have a pretty good idea of what you are trying to match.)

Cheers,
Tom

I just pull my two ladderlines off to opposite sides and fasten them to the edge of the roof about 4 foot apart keeping a little tension on the lines. That prevents the lines from getting too close to the metal mast or each other.

This is, of course, for a mast mounted such that it touches the edge of the roof and is secured there for stability.

Chris, I have 5 of them. 10, 15, 20, 40, and 80 meters. Living in a second floor condo with no outside antennas allowed I had little other choice. I have mine mounted on tripods in my dining room and guest bathroom and they work well. The 40 meter one works particularly well for my weekly schedule with WA9QNN in Grantsburg about 300 miles to the north. I have worked Alaska and Puerto Rico many times. I set them up with an MFJ antenna analyzer and use an MFJ 949C antenna tuner. I consistently get below 2.0 swr on all but 10 meters.
80 meters= 1.5 (very narrow requires tuning for any change)
40 meters= 1.3
20 meters= 1.1
15 meters= 1.7
10 meters= 2.5 (this one is in the bathroom, lots of pipes)

I ran the analyzer through the tuner to each antenna and wrote down the settings that gave me the lowest swr on each frequency I wanted to work.
80m= 2J4 on the tuner
40 m= 8D6
20m= 6B3.5
15 m= 6A4.5
10m= 6L6
These are set for the middle of the phone band.
80 meters is narrow but I just re tune by receiver noise, works great. Yes you would get better signals out from a full size dipole but I can't run one. I am very happy with my Isotrons. I was getting pretty tired of working only 2 and 10 meters.

Hope this helps. 73 Gary N9ZSV

Why 36 ft tall? That height is going to cause problems on the upper
bands as it's too tall. Take 10m for instance. Your takeoff angle will
be about 45 degrees. No bueno...
>

I've seen bundled radials being used before. I've never tried them
myself. The 36 ft radials would likely only be good for 40m. The
radials need to be resonant on an elevated vertical. Your antenna will
act like a different design on each band. IE: on 40m, it's an appx 1/4
wave. On 20m, it's two half waves in phase with a high Z feed.
Actually, it's a bit longer than that... etc, etc. I see lots of
problems cropping up with this design.
>
> Question #2:
> Should I have isolator/choke at the input to the auto-tuner to prevent
> currents flowing down the outside of the coax to my rig?

Not really needed on a 1/4 GP with resonant radials. But on the other
bands it could help I guess. Hard to say really. I've never tried
anything like this.
>
> Question #3:

> input of the balun. Would this antenna work any better?

I doubt it. Overall, this antenna is not a good design. I don't really recommmend. The problem is you are trying to get too many bands from a single elevated vertical. The 36 ft, is too tall for the higher bands. The operation of each band is totally different. In general you can only get two or maybe 3 bands at the most with an elevated antenna if you want it to function normally. When I had an elevated 40m GP up, I also used it on 17m as a 5/8 GP. I had a relay to switch in the matching coil for 17m. That antenna could function properly on only two bands. It could be used on 15m ok, but that was about it. It was too tall for 10m, the feed was too high Z to use on 20m without a remote matching unit. My appx 33 ft radials only functioned decently on 40 and 17. You can try this, but I wouldn't expect the greatest results. If you want good 10m performance, I would limit the vertical to 20-22 ft tall. Of course, then you need a coil to load 40m. Maybe the tuner can do this, but I don't know about the efficiency. You would be much better off feeding a balanced dipole with the tuner for 40-10 use I think. Normally, you can't multiband an elevated antenna unless you have a method of band changing such as traps, etc if you want "normal" performance. I see lots of problems cropping up on your design. Some pattern related, others common mode related, rf in the shack, etc, etc. I'd think of something else, or limit it to fewer bands so it can function properly on the bands used. MK

1882. Help building elevated vertical antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-13 21:28:58 UTC
From: robert fanfant <robertfa@microsoft.com>
Message-ID: <3bf190c1@news.microsoft.com>
Source record: 154835

GOAL:
I'm building an elevated vertical to be used on all bands 40 - 10 meters @ 100 Watts. The vertical portion of the wire antenna is 36 feet long with the bottom of the wire about 20 feet above ground. I have supports that can used to support 6 elevated radials at @ 20 feet high. I also have an SGC auto tuner that has a 50 ohm coax input, a single output lug and also a ground lug. I would elevate the auto-tuner at 20 feet and use the auto tuner output to tune the vertical portion of the antenna with the radials connected to the auto-tuner ground lug.

Question #1:
Does it make sense to bundle multiple lengths of insulated wire for each of my radials? Each wire in the bundle would be cut to the quarter wave length for a band of interest(i.e. each radial would consist of a wire for 40m, another for 30m,etc...? Or should I just have put up 6 radials with each radial being 36 feet long?

Question #2:
Should I have isolator/choke at the input to the auto-tuner to prevent currents flowing down the outside of the coax to my rig?

Question #3:
Another possible configuration is to use a balun. I would connect the vertical wire to one lug of a balun and the radials to the other lug of the balun. I would then connect the output of the auto-tuner directly to the input of the balun. Would this antenna work any better?

> characteristics ?

Yes again.

> what do you favor there !

Either will work ok. It depends...if you have loads of lightning
around, I would probably use the grounded coil. The problem with a
grounded coil is you can't use the antenna on it's 1/4 wl frequency.
IE: a 10m 5/8 gp can be used on 30m as an appx 1/4 wl GP if you use an
ungrounded coil. This won't work with a grounded coil. On the designed
freq, I'm not sure which is best as far as performance. Should be
little difference, but the ungrounded sounds a little "hotter" to me
on receive. But that may be my imagination.
>
> >Go to here: http://www.g4fgq.com/ to get a solenoid.exe program to
> >convert the mh into coil dimensions.
>
> got it..
>
>
> >> Approx distance from bottom to feed point.
>
> >Bottom of what?
>
> bottom of coil (grounded version I guess)

Not real critical as long as it's at the bottom somewhere. I usually
use a mount that has a bolt that the center conductor is connected to.
I attach one end to that bolt and clamp the upper end to the bottom of
the radiator with a hose clamp or whatever. "ungrounded coil". If the
coil was grounded at the grounded base, you would run a tap from the
center conductor to the coil and tap for best match. I usually use an
ungrounded coil most of the time. About the only time I use a grounded
coil is on a 5/8 mobile antenna. IE: 2m..I've used a 10m 5/8 gp on
30m, and I've used a 17m 5/8 gp on 40m, but that requires an
ungrounded coil. On the 40/17 version I used a 24 v relay to bypass
the coil for 40m use so I could get a good match in the fone band. MK

1884. Re: Using a slingshot to put up a dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-13 22:16:57 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3BF19BD9.5B0EAD23@eznec.com>
Source record: 154843

I've been doing this for many years for Field Day. I recommend getting a cheap Zebco rod/reel set. The Wrist Rocket slingshot is a good slingshot to use. The basic procedure is to tie a weight to the fishing line and shoot it over a tree. Then you remove the weight, tie twine to the line, and pull the twine back over with the line. If you need heavier rope, then tie the rope to the twine and pull it over with the twine.

I can put a line up about 100 feet using this method.

A few tips:
1. If you're working in the woods, paint the weight with fluorescent paint. Fluorescent fishing line is also helpful in leading you to where the weight fell.
2. I like about 8 lb. test line. It's heavy enough to not easily break, is limp enough to come off the reel without much friction, and you can get a decent amount of it onto a cheap reel. Fill the reel nearly full to minimize friction and maximize range. A tip I once got but haven't tried is to spray the reel bell with silicone spray.
3. Use at least one section of the rod, so you have at least one guide eye for the line. If you're alone, you can put it on the ground behind you.
4. For weights, I like to use 2 - 3 oz. Go toward the heavier end if foliage is thick, since lighter weights might not fall through. Large trees here are mostly Douglas Fir -- different weight might be better for deciduous trees. I use kind of teardrop shaped fishing weights, having the hole near the smaller end. Pyramid and spherical sinkers hang up when getting pulled over branches.
5. For nylon twine, I've recently begun using the woven line I've found in the tool department being sold as chalk or construction line. The common twisted twine turns as it's pulled over the branches, aggravating tangles. It's useable, though.
6. I use a fixed loop at the end of the fishing line. Put the loop through the hole in the weight, then put the weight through the loop. This lets you get it on and off easily. To tie the twine to the line, use a sheet bend knot. (A web search for "sheet bend" will get you a picture.) This knot is the least likely to hang up when you pull the twine over with the line.
7. Don't use this method for long term installations. The line cuts into the branch and pretty quickly gets stuck, and the tree grows over it. If it's up for very long at all, you'll never get it back down. You might have more time with hardwood trees, but not much at all with pitchy conifers.
8. If you're using this method in town, be aware that the weight can go a LONG way, and do considerable damage to whatever it hits.
9. There's a knack to it, with one of the critical issues being

placement of the weight in the slingshot pouch. Practice. And if you're away from home, take along a spare slingshot elastic or two. The line can cut the elastic on a fumbled shot.

I recently got a reel-slingshot combination designed just for this use. I've only used it a couple of times so far, but it works ok. It's a little heavier to pack than the separate slingshot and reel, but it's more compact.

Don't use the balun on the output side of the tuner!
A few beads on the coax would be a good idea.
Remember to run a real ground line from the tuner to the ground at the base
of the tree

It is a mismatch at the resonant frequency. The combination of dipole
+ twin-lead is best utilized for off-resonant applications (thru a
tuner) where the dipole may be closer to matching 600 ohm feed that
the normal 75 ohm feeder and the open-wire will have far less loss.

Hi All,

I have surplus to requirements an MFJ 989c 3kw ATU for sale.
I'm asking UKï¿½180.00 for it prefer buyer collects but will send via
snail mail if you are willing to pay the cost of postage.

Anyone interested please email me direct.

Cheers!

1888. Impedance of a dipole??

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-13 23:20:30 UTC
From: capra <bhyuu@spiritone.com>
Message-ID: <3BF1AABD.4E222A9A@spiritone.com>
Source record: 154837

Can I feed a center fed dipole with open wire?

I thought dipoles had a Z of 75 ohms. And that open wire
had a Z of 600 ohms. Isn't that too much of a mismatch?

I should have added the qualifier "at room temps". And you're right, all
metals are decent conductors, solid or molten.

Well yes, it's just that open wire or a particular geometry has a Z of
600 ohms. You can create it with an impedance of what you want by
varying the geometry. The diameter to spacing ratio should be about 1.2
(very approx) according to an old chart that I have. This'll give you
about 75 ohm.

Yeah, but the loss of the open wire, at HF freqs,
will be minimal. Use a "tuner" to match the radio
to
the feed line and forget it.
Bonus!!!! You get the capability to work other HF
bands with this set up. Do a search on:
"center fed zepp".

Source record: 154846

I too have been looking at vertical dipoles for 20 meters. However, my quick and dirty attempts at modeling this antenna suggest that the best takeoff angle is when the feedpoint is 1/4 wavelength above ground.

This leads me to use the resonant feedline dipole as described in QST and the ARRL handbook by James Taylor- just oriented vertically instead of the horizontal orientation suggested by the author.

In this setup, there will be a 6 inch coil with about 8 turns of RG58 at the base of the antenna (about one foot off the ground). The antenna functions with the coax carrying separate currents on the inside and outside of the shield - the coil then serves as an RF choke and it's position sets the "length" of one side of the antenna. The result is that the transmission line will be buried to the base of the antenna and the top of the antenna suspended from a tree branch at about 30 feet.

The models show a relatively low takeoff angle and a uniform azmiuth over all ground types from poor to perfect . If the base (coil position) is elevated, the zenith plot begins to develop additional lobes at higher angles.

So far this is all theory - I'll build the antenna shortly unless someone here can give me a reason as to why this one can't work.

Radio Shack HTX-202 2m HT excellent condx, both battery cases (AA & rechargeable nicads), speaker mic, manual,

Radio Shack HTX-242 2m mobile, some case scratches from being mobile, front panel is mint though. includes mic, power cord, mounting bracket & manual.

Open to interesting trades on both pieces. Looking for MFJ or Isoloop antennas, Yaesu desk mics, 10m SSB gear or whatever. Make an offer.

robert,
Since you want an 'all-band' antenna, which won't be resonant on most bands,
I'd forget about the varying lengths for radials. Instead, I'd add more radials
of
the same (longest) length, 6 probably won't be enough. Forget the balun, no
need for one. Ferrite 'beads' on the radio side of the tuner are not all that
effective
unless you have quite a few of them (as in 5 gallon bucket). A 'coaxial-choke'
may provide 'better' isolation, but considering the frequency range on which
you'll be using the antenna, nothing is going to be completely effective. Take
what you can get though...
'Doc

vtail,
A 'sling-shot'/'wrist-rocket' works just fine. I personally prefer
a 'potatoe-cannon'. Much better range. Safety is more important
than technique!

Since you are doing some modeling, add three more quarter wave radials set out at 45 degrees (total now of 4 radials) and run the model. I expect it will look better.

> Spam is what us Brits began to recieve from the USA in 1942 for
> which we are still very grateful. In return we presented the USA
> with the 3000 megacycle cavity magnetron and Loran.
==========

Just to tidy up the story about Loran and a bit more. The navigation system set up for RAF bombers over Europe around 1941/2 was at VHF. At the time it was more Top Secret than the atom bomb. The RAF equipment codename was GEE. In extreme conditions and a lot of luck it was possible to blind-land on return-to-base in thick fog after a bombing mission. But the main problem over enemy territory when under anti-aircraft fire or attack from nightfighters was the time needed for checking hyperbolic navigation charts in the heat of the battle.

When the USA arrived on the scene they shifted to lower radio frequencies for longer distance navigation. The Atlantic and Pacific systems were set up. The USA changed the name to LORAN = LOong RAnge Navigation. But the airborne equipment was contained in exactly the same size cases and was interchangeable between RAF and USAF aircraft. Only the operating frequency and navigation charts were the essential differences. There were of course engineering differences in valves/tubes. The Brits used pentodes, VR65's and EF50's. The Yanks used double triodes, 6SN7's 6SL7's, because of the lower frequencies involved, including CRT time base. The number of different types of tubes for mainenance purposes was very much reduced.

I worked with both airborne RAF GEE and USAF LORAN equipments. When in the Far East, in the Pacific Ocean region, I remember the problem with the lower freqency LORAN was multiple reception of the transmitted pulses due to multi-hop transmission paths via the E and F ionospheric layers. The navigating officer's problem was choosing the correct pulse out of the many pulses received randomly distributed milli-seconds apart. Remember there were at least 3 pulse transmitters, one master and two slave stations, on every system. Shipborne navigation officers had more time to think about it before advising the ship's captain which course to take. But I have myself been severely reprimanded by the aircraft commander for the agonising length of time taken to tell him whereabouts in the China sea lay the target. (But that was not Loran). It hurts !

It must be added, at the time the German and Japanese radar systems were quite advanced. The GEE system was prone to German jamming and it was easy for an aicraft to get lost - specially when the crew

had forgotten how to navigate by sextant and the stars. On one poor-weather night in 1943, clouds all over Western Europe, when there were 1000 RAF bombers in the air, all of which were depending on GEE for navigation, the Germans switched on the jammers and 110 aircraft never returned to their bases. Most crashed running out of petrol. Others landed in Sweden, Russia and North Africa.

A prolonged loss of more than 10 percent of the bomber force every night, due to air battles or just getting lost, was intolerable. The aircraft factories in Birmingham, Coventry and Manchester could not possibly turn them out fast enough. The loss of trained aircrews was equally intolerable.

It was not until the 10 and 3 centimeter cavity magnetron radars came fully into use in 1944 were navigation and target-finding problems solved and the enormous losses of shipping due to submarine attack in the North Atlantic were reduced to acceptable proportions. The merchant shipping losses at sea had sometimes amounted to more than 15,000 tons every day, including the terrible loss of complete ships' crews.

When in a N.Atlantic convoy, to heave-to to pick up out of the water the crew of yet another sunken ship was to commit suicide. So nobody stopped. Indeed the British merchant navy crews, who were civilians and whose wives and children received no military pensions, suffered more deaths than any other of the British armed services. These 110,000 unsung Hero's were first belatedly represented at the National Remembrance Day Cenotaph ceremony, Whitehall, London, only last year, 55 years too late.

As a tribute to the ordinary British working man and woman in the shipyards it should be said that when WW2 began the British Merchant Fleet was 20 million tons - the world's largest. 20 million tons was sunk, mostly in the North Atlantic. At the end of the war the British Merchant Fleet was still 20 million tons. There had been some assistance from Henry Kaiser's USA Liberty ships.

The other Hero's who have watery graves at the bottom of the North Atlantic are German submarine crews who in the last 9 months of the war were well aware they were on Kamikazi missions. What a stupid war ! Only one country benefitted.

Thanks for all your answers

I have been offered another idea wich is to put up a rigid dipole for 10-40 (Cushcraft D4) on a small mast with rotor. Not quite clear: I don't know how will one of this work at low height (3~4 m = 10~15 ft) over the roof.

In any case thanks again for your opinions.

Ed Laport, in "Radio Antenna Engineering" promotes wehat he calls the "Logarithmic-Potential Theory" as a simplified method of determining Zo.

Ed notes that I=vQ where I is the current in a wire, v is the wave velocity, and Q is the charge per unit length.

When v is a constant, I is proportional to charge, and charge ratios become current ratios.

Ed notes that in almost all practical r-f transmission lines, Zo=sqrt L/C, and since v=1/sqrtLC, Zo=1/vC.

Ed derives Zo formulas for one wire above the earth, a 2-wire balanced line, multi-wire lines with some wires grounded, and lines with noncylindrical conductors.

Ed says Zo can be found for lines with conductors of any arbitrary shape by using successive steps. He gives examples.

Everybody needs a copy of Ed`s 1952 McGraw-Hill book.

Best regards, Richard Harrison, KB5WZI

Reg wrote:
"Just to tidy up the story about Loran and a bit more."

Reg was obviously the electronics operator aboard a WW-2 RAF bomber. Three cheers for him. They won.

I recall listening to those medium-wave swept-frequency pulses just above the AM broadcast band that Loran used.

I was rated and served the U.S. Navy as a diesel engine mechanic in WW-2. On my ship in the Pacific, I was also the only electronics repairman. We had an electronic fire control computer, friend or foe identification gear, FM and AM communications, and a Raytheon SO-2 navigational radar (thanks in no small part to British ingenuity). Our spare magnetron was considered secret and kept in the ship`s safe.

I was given the electronics work because I was the only one aboard who could do it. I had taken an NRI correspondence course and had a lot of experience fixing radios before joining the navy. My most important work in the eyes of the ship`s company was keeping the movie projector going, come hell or high-water. Forget the fire-control computer. We had a terrible AAA record with or without the electronics. My GQ station was on a duplex 40mm gun.

Post-war, thanks to government subsidized veterans education (GI Bill) I got an EE degree.

Best regards, Richard Harrison, KB5WZI

Good afternoon, CAM.

What about if you're running ladder line to a Nye Viking type tuner
(in the shack) and coax from there to the transceiver? Do you still
need to make sure that the feeder is 1/2 wavelength or multiple?

Thanks...

Rick

1909. Butternut HF2V + SGC SmartTuner = All-band vertical?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-14 17:45:03 UTC
From: vtail@hotmail.com
Message-ID: <3bf2a9bd.104878744@news.netis.com>
Source record: 154862

I am considering installing a Butternut HF2V 80 & 40 meter vertical, up about 30 feet at the base, with at least two (preferably three or four) quarter wave radials on each band of interest.

(Can't do a ground mount with a gazillion buried radials; must do above-ground mount.)

My question is: If I install an SGC SmartTuner automatic antenna coupler at the base of the Butternut vertical, and feed the vertical with as short a wire out of the SGC coupler as practical, can I then use the vertical on all bands 80-10 with reasonable results?

Has anyone tried this, and if so how well did it work?

I will also have a 160-meter inverted V fed with open wire feeders, up about 50 feet at the apex, and plan to use it with another (Nye Viking) antenna tuner for 160-10. My plan is to use the inverted V for shorter-range skywave stuff and the vertical for longer-range DX on 80 and 40, the expectation being that the vertical should have a considerably lower angle of radiation on 80 and 40 than will the inverted V. Does that sound reasonable?

(I don't anticipate a big difference in performance on 20-10 between the inverted V and the vertical at most distances, the idea being to switch between them on a case by case basis and use whichever one gives the stronger received signal.)

Thanks...

Rick

I'm looking for a small antenna that I could put up with only one support, like an M-Squared 6 meter square loop antenna. Does anyone have one in good condition that they'd like to sell? If so, how much?

Or, are there other good performing 6 meter horizontally polarized antennas that only require one support and don't take up a lot of space?

Thanks for any help in advance.

Reg wrote:
"What a stupid war! Only one country benefitted."

Which country would that be?

It certainly wasn`t the U.S.A.. The U.S. aided and abetted the Allies bercause it saw the Axis as aggressors which were clear dangers to the U.S.. The Japanese on December 7, 1941 showed the U.S. correct in its concern.

The U.S. had been turning-off Japan`s oil to reduce Japan`s military capabily which had already tortured much of Asia while sloganizing with "Asia for the Asians". Of course, by Asians Japan meant Japan. On December 7, 1941 the U.S. was at peace with the world and trying to stay at peace.

Admiral Yamamoto who lead the Pearl Harbor attack is quoted as saying on 12-7-41, "I think we have awakened a sleeping giant". The attack on 9-11-01 was very similar in that respect.

The WW-2 military victory did not benefit the U.S.. Graves of fallen GI`s around the world exhibit the worst loss of the U.S.A.. My own brother is still in his submarine at the bottom of the Pacific. The U.S. emptied its treasury and assumed a huge debt so Ford could for example roll B-24s off its assembly lines every few minutes as if they were automobiles, and other war materials could be produced in similar abundance.

The Pacific Fleet on the bottom at Pearl Harbor was no benefit to the U.S..

The U.S. brought back no spoils of war. It instead went to work producing relief for countries devastated by war, friend and foe alike, only to find itself struggling with yet another oppressive regime determined to spread its domination.

Ever since WW-2 the U.S. has spent its blood and treasure to preserve freedom. Korea, Viet Nam, Bosnia, etc.. Like Afghanistan, none of these places has any great importance. The expulsion of Iraq from Kuwait was in the U.S. economic interest because Iraq threatened Saudi Arabia which is the world`s major oil producer. Iraq`s invasion of Kuwait was so blatant and Iraq was such a bad actor for its own population and neighbors, that most of the world either joined the U.S. in its cause or cheered it on.

The U.S. often feels victimized by British policy. There was (Arthur) Neville Chamberlain who said it would be OK for Hitler to take the

Sudatenland. That sharpened Hitler`s appetite for territory. Then, during the conflagration that was triggered, Winston Churchill promised jews a homeland if they would cooperate in WW-2. Who were they going to support? Hitler?

Hello!

I am contemplating putting up a Cushcraft X7 tribander and an A3WS 12/17m yagi. Obviously, the more spacing the better. But what would you say should be the minimum?

The grand scheme is to have three yagis on one mast:

Using a 22' mast, I would put a 3 ele 40m yagi at the bottom, X7 8' above that, and the A3WS 8' above that...Thoughts?

73,
Ed

Rick, I own an SGC239 autotuner for my random wire. Their manual shows it also being used with a flagpole with at least three counterpoise wires equal in length to the height of the flagpole. Instead of the Butternut, maybe some plain old aluminum tubing?????? As far as the tuner; it seems to work great with my 60 foot random length. It loads up on practically any band I've tried.

Referring to your questions:
#1 Same length radials -- this per your SGC manual
#2 A coaxial choke is a good idea
#3 Forget the balun -- again SGC doesn't indicate their use at all in their manual.

The 40 meter yagi needs the most height. If you can put it on top, do it.
Do you already own the Cushcraft X7 tribander and an A3WS 12/17m yagi?
If you do, split the separation by as much as your tower and mast will
allow. If you don't you might consider another antenna that gives you all
the 20 M - 10 M bands, like a TH-11. There are way too many variables here
to give a simple answer to a very complex solution.

Reg wrote:
"But I have myself been severely reprimanded by the aircraft commander for the agonising length of time taken to tell him whereabouts in the China sea lay the target."

After U.S. Admirals stopped fighting WW-1, they agreed convoys made sense. My ship was often part of a convoy. The bridge watch was drowsy like everyone when we were underway in a war zone. We had scheduled watches, dawn and dusk General Quarters, and a regular turn-to work schedule during daylight hours. There was little if any time scheduled for sleep.

In convoy, someone on the bridge would awaken from a cat-nap and realize we were about to ram the ship ahead of us. He would scream through the voice tube to the radar operator for a distance to the ship ahead. Sea return made short-distance measurements impossible. So, the operator would arise from the Plan Position Indicator (PPI) tube and go poke his head out a porthole, then return to the voice tube, to scream his best estimate of the distance, back to the bridge. I swear this was the usual procedure.

The radarman answered not because he knew, but because he was asked. In the navy there was only one acceptable answer, "Aye, aye, sir".

Bill Orr's (RIP) "Radio Handbook" is for me the definitive reference
and teaching aid for the science of basic electronics/mathematics as
applied to amateur radio. My twentieth edition (1975) is a well worn
treasure if only for the characteristic curves of vacuum tubes; but of
course it is much more. Many thanks to Bill and all who assisted.

Make room in your library for this "Editors and Engineers" (HW SAMS
Co.) volume if you can find it through web-based 'used' book dealers
or your local swap meet. For the bibliophiles out there, the ISBN of
my volume is 0-672-24032-7.

Thank you, Bill.

Hi, Rob. I use am elevated vertical dipole of sorts: aluminium whip 26-feet long (a wire hung from a tree would work just as well) with a single 26-foot radial pulled away at a slight angle from the open wire feedline. Works fine all bands 80-10 metres.. Tune it with a Johnson Matchbox (doesn't quite do 1:1 SWR on 75-80, so I go through a Drake MN-2000 tuner and then through the Johnson Matchbox on this band). Run 100 watts from a Drake TX4-C. First QSO was with a bunch of Gs on 75-metre phone in the early evening. Might be an idea to stop worrying about exact matching to 50-ohm coax and go the open-wire feedline route. Much easier! 73. Harry, VE3GRO

Good evening, Karl.

Well, a couple of reasons for using the Butternut instead of a length
of aluminum tubing.

First, I already have the Butternut.

More importantly, though, a quarter wave vertical for 80 meters is 63
feet high, more or less. The Butternut is 32 feet or thereabouts.

Of course I could just put up a 32-foot length of tube and feed it via
the SGC and have an antenna the same height. But, the Butternut is
already resonant on 80 and 40 and so the SGC tuner would only be used
to extend 1.5:1 SWR to the band edges without a lot of coax losses.
The performance will be what it is, probably the same as any quarter
wave vertical on 40 and a bit less than a full quarter wave
performance on 80.

It's 20-10 I'm mainly wondering about ... can I expect good
performance on these bands?

Of course, the other question is, the Butternut vertical is made to be
fed directly with coax ... if I stick a coupler in there will that
screw up some design feature of the Butternut?

Rick

Good evening, Ron.

I'm going to have to work on making my posts to these newsgroups more clear, I think.

There are NO plans to skimp on the counterpoise.

However, EVERY text I've read on vertical and ground plane antenna design, including the ARRL Antenna Book, has made the point that a ground plane antenna whose base is more than a quarter wavelength above actual ground gives performance with four quarter wave radials that is as good, for all practical purposes, as a ground-mounted vertical with all those 120 buried radials everyone seems to recommend.

My installation won't be a quarter wave above ground for 80 meters, but will be more than that at 40 meters and beyond.

I may put up four radials for each band, sloped downward to make the feedpoint impedance more nearly 50 ohms. I haven't decided that yet. My bet is that three radials for each band will yield performance that is negligibly different from that with four radials per band. But, if the experience of anyone here is different, I'd appreciate hearing about it.

My objective, though, is to be able to use this 80 and 40 meter vertical on 30, 20, 17, 15, 12, and 10. Hence, the SGC coupler ... which I would mount at the antenna feedpoint, per SGC's recommendation, so that I don't just tune out a high SWR on the feedline which still results in a lot of feedline loss.

My questions are, is there some design aspect of the Butternut that I'd screw up by installing the SGC coupler at its base? ... and, can I expect reasonably good performance at 30 meters and beyond with this setup?

Rick

> >had a Z of 600 ohms. Isn't that too much of a mismatch?

Nope, it's not "too much of a mismatch". That SWR is 8:1.
On the lower HF frequencies, an SWR of 8:1 on 100 ft. of
open-wire transmission line results in negligible losses due
to SWR. In fact, an SWR of 8:1 on open-wire line will result
in lower total losses than an SWR of 1:1 on many types of coax.

When a vertical "monopole" is much more than 5/8WL long, it
develops high angles of radiation which is generally the
opposite of what you want on the higher HF bands. For instance,
a 33ft vertical monopole that is resonant on 40m is generally
useful up through about 18MHz but no higher. If you take the
resonant frequency of a 1/4WL monopole and multiply it by about
2.5, you will get the upper frequency limit, i.e. 5/8 divided
by 1/4.

If you use a parallel coil instead of a parallel capacitor, you usually
won't have to switch it in and out because the impedance of the coil
increases with frequency. For normal QSOs, you won't be able to tell
the difference in performance between using a matching cap or a matching
coil.

Either method will work. The base capacitor causes the screwdriver to use
slightly more coil. The base inductor causes the screwdriver to use
slightly less coil.

Take a look at the No-Tuner All-HF-Band Antenna on my web page.
It works well with internal autotuners.

If I feed a dipole with open wire will today's radios autotune
to it?

Will a dipole cut for 80 meters and fed with 50 ohm coax
autotune as easily as same antenna fed with open wire?

Will it perform any worse?

I'd like to center feed a good sized dipole with open wire
and autotune it with a 756pro?
Will this perform well?
Or will the 50 ohm job perform a lot better?

Can I use a BALUN of some sort to change the feedline
back into 50 ohm coax to go into the house?

Basically I guess what I'd like to know is how good these new
radios autotune and how much antenna performance you lose
autotune an antenna like this.

It would be nice to have one antenna that the radio could autotune
to and work well.

1940. Re: MEASURING SWR

A TDR is a poor instrument to use for measuring impedance or SWR of an antenna system. Both are functions of frequency, and you don't get this information directly from a TDR. In some cases, it's possible to derive SWR and impedance with the use of software, but this is practical only with a TDR system having an output that can be digitized. Even then the results are likely to be less accurate than other methods.

This is about the same scenario as the 36 ft elevated vertical in
another post.
It can work, but that antenna is too tall for 12-10 meters to have a
good low angle takeoff. It would be about 40 degrees. Now, if this
wasn't a problem, I guess it could be ok, but it kinda defeats the
purpose of a vertical. That 32 ft antenna would work well up to 17m,
and ok on 15m. On 20m the feed will be high Z at the base, and the
results will depend on the efficiency of the tuner at handling hi Z
loads. BTW, that antenna at 30 ft will work pretty well on 40m with 4
radials. Decent on 80m. You have to remember that 80m would need 8
radials to equal the 4 radials used for 40m if all are at the same
height. So if you use only 4 on 80m, the performance on 80m will be

less than 40m. On 20m as a halfwave, you really don't require radials to function, but you may need to consider line decoupling. On 17m , you would have a 5/8 gp, and would need radials. On 15m, it's about 3/4 wave, and also needs radials. 40m radials can double for 17/15 meters fairly well. I'd forget about 12/10 meters. it will be lousy. In fact, I tried it once on a 32 ft 40m GP at 36 ft with a tuner , and it was lousy. MK

It will tune easier, as it's impedance will be around 75 ohms, which is no
problem for an autotuner.

> Will it perform any worse?
>

Depending on feedline losses, maybe.

> I'd like to center feed a good sized dipole with open wire
> and autotune it with a 756pro?
> Will this perform well?

The "pro autuner has a tuning range of about 3:1. See previous comments.

>
> Can I use a BALUN of some sort to change the feedline
> back into 50 ohm coax to go into the house?
>

Sure can. That's exactly how I designed my multiband dipole. It is feed
with a length of 300 ohm ladder line, through a balun, to LMR 400 coax. My
Pro tunes all bands fine on this antenna however it is not a typical half
wave dipole. I designed it so that any one band would be within a 3:1
match. To do this took a lot of experimenting with the combination of
dipole and ladder line lengths.

There are a lot of good programs on the web for doing the basic
calculations, the one I used was called DIPOLE1 by G4FGQ. You can get this,
and many other useful programs at
http://www.btinternet.com/~g4fgq.regp/page3.html#S301 .

> Basically I guess what I'd like to know is how good these new
> radios autotune and how much antenna performance you lose

They tune fine within their design limits. However, you do lose about 10% of your power in the tuner, and possibly more depending on the feedline losses and actual SWR at the antenna.

I tried several variations on the slingshot/spinning reel theme and
could never get usable results despite the fact that others have
apparently been successful with this approach. I ran into two primary
problems: Monofilament fresh-water fishing line has "memory" and I
found has a distinct tendency to coil and tangle itself in tree
foilage. The other problem I ran into is that fishing weights in the
ounces category do not have enough weight to the pull (self-tangled)
monofilament line back down to ground level after the shot. It's a
simple friction vs. weight Newtonian mechanics issue. There are still
some large number of my fishing weights still "decorating" trees
hereabouts which attest to my failed atempts to get the slingshot
thing to work.
>
>
As a related aside, there is some guy out there advertising a wrist
rocket antenna launcher in the ham mags for around fifty bucks. The
same slingshot is available at any K-Mart for $7. A K-Mart spinning
reel is another $7. Plus another $4 bucks for some monofilament line,
weights, an "angle iron" corner bracket and the four hose clamps which
attach the reel to the slingshot.
>
>
I got tired of decorating trees and decided to go into brute force
mode. I popped $125 for a used 60 pound pull compound hunting bow.
Some bow hunters hunt for fish. Bow fishing reels are out there for
(once again) $7, they screw right into hunting bows. I filled the reel
with a hundred yards of 80 pound test braided (no memory)offshore

leader line. Sticking with the bow fishing concept I bought a couple blank (no arrowheads) fishing arrows for five bucks a pop. These are different from the usual light hollow deer hunting arrows, they're heavy solid fiberglass. I attach the line to the arrows via the holes in the arrows which are right behind the fletches. I wound balls of 3M rubber electrical around the front end of my missles for safety's sake and to get the weight up. I painted the arrows flourescent orange per another post in this thread. I ran into some glitches which I resolved, if you're interested in pursuing the details we can take it offline kelly@dvol.com.
>
>
The bottom line is that this this rig can blast thru or over any tree we have here in the Northeast including any of our monster leafy old hardwoods. With ease and I get an 80 pound test line back down on the ground every time where I can get my mitts on it. Typically 100 feet on the other side of the tree.
>
>
There is of course The Mother of All Aerial Launching Slingshots floating around here. I dunno who he is and I've never seen his legendary monstrosity but somebody in this area has some kinda monster two-man slingshot or some such. He shows up on Field Day and fires wire all over the county with the bloody thing.
>
>
And by the way I really like the potato gun concept, gotta try that! Izzit type accepted yet?

Yes Ric, looking back, it's so funny to remember how voice tubes and magnetrons worked so well together. At the time, of course, it was often deadly serious.

Just a minor correction - I was not a bomber crew member, I was radar maintenance. But I did a fair amount of flying - always in flying boats, first twin engined Catalinas and then 4-engined Sunderlands. Took my turn in the radar cabin. Never even saw a parachute - there was never one on board - so a little uncomfortable when flying over mountains on automatic pilot and the flight deck deserted. ;o)

Source record: 154798

The slingshot line is used to haul up a braided mason's line or a
skinny Kevlar line which then can haul up the line number 2 which
supports the pulley, as detailed below.

Describing one end of a proposed antenna suspension system, starting
at the antenna wire:
Antenna wire, then insulator, then braided support line number one
which passes through the pulley. Secure other end of braided support
line number one to a counter weight or use one of the other
arrangements described in ARRL Antenna Book. Or, as Alan suggests,
make line number one a loop for easier servicing. Line number one
should be braided so it behaves well when running through the pulley.

The pulley (called a "block" at the ship fitter's store) is tied on
the end of line number 2 (either braided or twisted) that passes over
a branch or fork in the tree then proceeds down to where it is secured
to a screw eye. Line number 2, where it passes over the tree branch
or fork, is run inside a 4 foot length of liquid tight flexible metal
conduit. If the tree grows tight around the flex conduit, no great
problem, as line number 2 moves freely inside the conduit, allowing
adjustment or pulling a replacement line into position. The screw eye
where line number 2 is secured is a long stainless steel screw eye
driven into the tree trunk 10 ft above grade. Inspect the screw eye
every year and back out the screw eye a little at a time if necessary
to compensate for the tree growing in diameter.

Good morning, CAM.

Well, I guess it doesn't make much sense for me to spend $400+ on an
SGC antenna coupler just so I can use the Butternut on, say, 30 meters
and maybe 20.

OK, thanks to you and to all the rest of you for your usual array of
good advice.

OK Roy.
Everything You say is of course correct!!

I personally do NOT want to measure SWR this way. But this
guy wants to measure it without going "on air". With 0 pW RF.
What is the "nearest eqivalent method" of doing a SWR
measurement without emitting (=zero, or as small as possibe)
RF?

capra,
Your autotuner probably won't tune the dipole fed with an open-wire feed line. The input impedance of the antenna isn't going to be anywhere close to 50 ohms with the open-wire feedline (probably), and most autotuners just won't handle impedances very far from 50 ohms. That's the 'short' answer.
There are ways of making it work, though. Those ways are not simple, like hooking up coax, punching the tune button, and talking.
If your not wanting an 'all-band' antenna, but just want to change the 'looks' of your antenna, there's no real benifit to using the open-wire feedline.

Jerry,
The short answer is, no, there's no way of conveniently measuring
SWR with out transmitting ~some~ power. There are ways of keeping
that power to a very small (negligible) amount. One way is to turn
the output power of your radio down to a very small amount. Another
is to use one of the antenna analizers, which usually only use milliwatts
of output power. Measuring SWR doesn't require much power output,
but it ~does~ require some power.

Help
I'm trying to fathom out the circuit of an ATU made by Racal Positioning Systems, it's a type 90516 and I believe it was intended for a mobile positioning/navigation system on 1.7-3.4MHz (DGPS/Deltafix etc).
The unit consists of a large central inductor 65 x 112mm, 35 turns with rotary switches selecting taps at each end through concentric shafts, the input seems to select a small number of turns at the earthy end of the coil and the output selects larger bits at the output end of the coil to which is connected a vacuum variable capacitor (8-650pF) to earth, a second vacuum variable can be put in parallel with the first via a reed relay and the unit seems to be dual frequency because there's some switching marked F1/F2 on the front panel and the two variable capacitors are marked F1 & F2. I'm assuming that the system is used to tune a "short" vertical, the unit is enclosed within a tightly screened box inside a fully gasketed outer case and is wired in 30Kv HT cable, the RF inputs and outputs are coaxial LEMO (Swiss) connectors.

I'm having difficulty drawing out the circuit because most of the links to the rotary switches run inside the inductor and continuity checks don't help, can anyone suggest what circuit configuration the unit may have?, I'd like to put it to use as a general HF ATU but I'd like to avoid making too many changes.
The ATU also has an electronic RF ammeter and came with a type 90512 PA, I'd be grateful of any information or pointers to circuits/specifications etc.

Thanks

John

If you are not concerned about the "windows" ordinary television lead in line works fine. I use it for my 100 watt radio, and have been using it for 25 years.

The window style, which is very close to Ladder line is sold by most of the "wire" vendors on the internet. (such as http://www.cablexperts.com/) It is essentially the solid dielectric tv line with holes punched in it. I used some this year for field day because I could order it by the foot and get a 150 foot piece. At Radio shack the longest piece they sell is 100 feet of the foam core stuff, which is what I usually use.

I do a very similar thing, but instead of the ship fitters store, I went to the hardware store and bought garage door pulleys and springs and galvanized wire rope.

The first one I put up I used regular rope, and it failed after a couple of years. This one is with the wire rope, both holding the pulley, and tensioning the antenna.

I use a "70 pound" garage door spring and two pulleys instead of a wieght, and end up with 7 feet of travel and 35 pounds of tension on the antenna.

> meter or something?

Guess I'd say, "yes, with some qualifications" to the first question.
I'd assume for SWR that you the know the Zo of the line you want to
know the SWR on, and that the thing you want to measure is a "linear
system" and it is the source of some power...for example a received
signal. In theory, if you adjust the load (your instrument) to
maximize the power it receives, then it's impedance will be the
complex conjugate of the load impedance. And the load impedance
combined with the line Zo will tell you the SWR. In practice, if it
were really important to do this, I'd probably look at ways to
accurately measure the power while quickly switching among some small
set of load impedances, to be able to make sure the received signal
strength wasn't changing too rapidly. You WOULD be at the mercy of
having some reasonably stable power to look at, though.

But it would be a lot easier to do by sending some power down the
line. It doesn't take much power; you can use a sensitive receiver as
the detector. In fact, the old noise bridges use this to advantage:
use a noise source (or could be a very low-power CW source), and
adjust the bridge for a null in the receiver. A narrow receiver could
presumably detect a few nanovolts with no trouble, so your source
could be as little as a microvolt and still get 40dB directivity, not
too shabby. I don't think I'd call transmitting a microvolt exactly
"going on the air" though someone next door listening on just the
right frequency might be able to hear it! Network analyzers, which do
this sort of thing nicely, have calibrated receivers that aren't
generally terribly sensitive, but still don't require much power
(generally adjustable from a few milliwatts on down to perhaps
nanowatts) to be sent to the load in order to get accurate impedance
measurements of the load.

Cheers,
Tom

Mike Powell wrote:
"Not confusing this with the Balfour agreement are you?"

I believe Churchill`s promise was a WW-2 resurrection of the Balfour Declaration.

The Balfour Declaration was addressed on 2-November-1917 and promised British assistance in establishing a Jewish National Home in Eretz-Israel, but stipulated that civil and religious rights of non-Jews be protected.

Britain wanted sole supervision rather than joint supervision with the French as had been previously planned. That prompted the Balfour Declaration. Britain had too speed release of the Balfour Declaration because the Germans were about to declare their own support of Zionism. Maybe American support for the Balfour Declaration doomed it. Woodrow Wilson was a big supporter.

Today, the American position must in favor of a strictly secular state in Israel as in everywhere. The U.S.A. must be categorically opposed to any religious state beyond something like the Vatican. The American Constitution is founded upon strict separation of church and state. U.S. money is imprinted with:"In God we trust.", but relations between government and churches are almost hostile. The American Constitution insists on equal rights and equality under the law for all, including atheists, as it must for true equality and freedom.

The theocracy that Israel wants to maintain must be as odious to Americans as a government by mullahs in Iran or in Afghaniistan.

Best regards, Richard Harrison, KB5WZI

I don't know whether you mean that everything I said about TDR is correct (I believe it is) or everything I say, period, is correct (it certainly isn't). If you do a search of my postings with Deja, it shouldn't take long to see that I say plenty of things that aren't correct. The really great thing about this form of communication is that when I do, it's easy for people who do know the right information to post a response to set things straight. And they often do. Because of my background, TDR is a topic I do know quite a bit about. But there are still a lot of things I don't know about it, and always welcome corrections to what I post.

As an answer to the poster's original question, I agree with what Doc and others posted -- you've got to create some signal to measure impedance and SWR, but analyzers and bridges use small enough signals that they're not likely to generate interference.

Incidentally, a TDR also generates a signal. A high speed TDR having a rep rate of 1 MHz (they typically run from tens of kHz to a few MHz) puts out a signal every MHz, extending to as high as 50 GHz or more. Because it's so spread out, there's not much at any one frequency, but the signal is there.

I have heard many rumors about California having some of the most harsh zoning restrictions for antennas and towers. I am considering taking a job with a company in the lower Bay Area, and plan on buying a house. Realizing the high cost and lack of suitable properties in the Palo Alto area, my search area includes all the way south to Watsonville and mostly all of Santa Clara County. In other places I have lived, you generally don't have restrictions unless you are located within a city/town municipal boundary. Outside town in unincorporated areas of the county all you need do is satisfy the building code. Are there any areas within reasonable distance to Palo Alto (let's say 60 mile commute) where I can have a nice tower and erect antennas to my hearts content? (I have 120 ft now and would like to put all of it up, but of course I need a lot big enough, so land cost is a big factor!) It's generally my belief that I won't make a town rich collecting my taxes if I don't have reasonable right to pursue my hobby, so if it's too restrictive I'll go somewhere that isn't, regardless of how much money I can make in Silicon Valley!

Thanks Tom for your input.

I do agree with you about various interaction when antennas are concerned..
Maybe my choice of word wasn't the best "Optimum match" would have been
more like it.
See..What I had in mind when I asked the question about 5/8th wasn't so
much just for me.. as a ham, if I'm forced to do it!
I can do some calculations.;-)
But from a newbie point of view even though there is countless design or
pages even prgs. for dipole yagis and the likes.
5/8 "with its matching coil calculation" seems a bit forgotten..
That's all.
Sure as G4FGQ pointed out (about it's prg) in a private email.
(Which i still have to answer)
coil design such as length, diameter, etc.. Is your problem.
I thought that for a new ham having a specific prg for 5/8th which would
require only frequency.
and then spit out "radiating element length and "optimal" coil
characteristics
still letting you input variable if necessary "Would be Cool"
That's all..
Wish i had kept on going playing with basic after the commodore 64 ;-)
Could have done it myself.

All the best
john VK2FAH

Hi Tom,

Generally if you are using 3 or 4 radials, and if they are at a 45 degree angle, the antenna will perform well if the radials are about 5% longer than the radiating element.

With a "DL' call sign, I suspect that you may only have access to the 144 to 146 segment of the 2-meter band (The USA 2-meter band is 144 to 148 MHz). That being the case, your radiating element should be, in metric measurement, about 48.8 cm (19.24 inches).

The radials would be, in metric measurement, about 51.25 cm (20.2 inches).

Assuming the antenna to be truly resonant at its design frequency, you can make some adjustment to the radiation resistance by changing the angle of the radials, though it should work quite well without this "tweak."

73,

Wayne, W1KI

Did you try it with a known good dummy load?

My TS-450S/AT has an "auto-tune" button which, when pressed, initiates a tuning cycle. If your 440 has one, and when you're on 40m and press it, do the tuning motors make any sound at all? If it's making no attempt, that's one problem. If it tries but never gets down to 1:1, then there's something open (probably) in the tuner board.

Are you sure you're within the 40m band, because it won't tune or transmit outside of the legal limits unless you or a previous owner have modified the rig.

If you have access to a service manual, there may be a mode you can set the rig in that will let you adjust the tuner manually. I can do that to a limited degree with my 450.

There are lots of small relays all over the tuner board that switch coils and capacitors in and out as you change bands. A failure of any of these will keep the unit from tuning properly, although I'd at least expect it to try. You should hear the relays clicking as you change bands, but because several usually turn on and off for each band, you won't necessarily notice if one isn't working.

Any further diagnosis would require a service manual. This is why I bought mine when I got the rig 10 years ago.

If all of the above fail, I guess you just have to get it fixed, because it's broken.

Helpful, ain't I. Sorry, but since the whole thing is controlled by the microprocessor, a repair could be expensive.

If you have a tuner go the Antron 99 route. Its a stick. I use it from 10 meters(6 with luck) to 40 meters with a tuner. The same antenna has been up since 1988 or so)
Without a tuner use a GAP Titan. The Titan does have a counter poise have both in operation. I started with the Antron and when I upgraded to General got the Titan(Good from 80 to 6 meters) I have used it on 160 meters and understand one ham in the area uses it on 2 meters(I cant). No turner required or sugested.(I have had it up and in use since 1990 or so)

>
> Will it perform any worse?
>

That depends on the frequency. If you are using it on
80 meters, 50 ohm coax will give a better match: i.e. it
will tune more easily. The actual impedance of a dipole
is usually somewhere between 25 and 100 ohms depending
on how far above ground it is, so 50 ohm coax may give an
excellent match.

A folded dipole will have an impedance that more closely
matches an open wire feedline. In either case, the open
wire line will have less loss, which may be important if
you operate it on frequencies that produce a high SWR.

> I'd like to center feed a good sized dipole with open wire
> and autotune it with a 756pro?
> Will this perform well?
> Or will the 50 ohm job perform a lot better?
>
> Can I use a BALUN of some sort to change the feedline
> back into 50 ohm coax to go into the house?
>

Yes, but the balun must be designed to handle the high
reactance it is likely to see, i.e. it will be seeing
high current and/or high voltage. It would probably
be wise to use a balun designed for much higher power
levels than you are actually using, unless it is
actually specified for your power level when handling
high SWR. Again, how high the SWR is depends on what
frequency you use it on, so you might be able to ignore
this. The most important factor (I think) is that the
core must be large enough to not saturate at the highest
currents it will be handling. Even with an air-core
balun (which can't saturate) the wire sizes used must
take the potential high currents into account.

> Basically I guess what I'd like to know is how good these new
> radios autotune and how much antenna performance you lose
> autotune an antenna like this.
>

They usually can't handle more than 3:1 SWR, so you need
to design your antenna system so the impedance presented
to the radio is within that range. I don't know how lossy
they are, but since the tuners are small, they probably have
significant loss.

> It would be nice to have one antenna that the radio could autotune
> to and work well.

For that, the G5RV should be a good start. See
http://www.qsl.net/aa3px/g5rv.htm for more details than
you may want, but the second half or so of the
article includes construction details. You might get
better results if you use a 4:1 balun between the twinlead
and the coax, but it will need to be a heavy duty balun as
mentioned above. Also, I don't agree with the statement
that the impedance of the matching section doesn't matter.
It's true that it won't much affect the performance of the
antenna, but it should change the impedance your transmitter
sees, so a little experimentation might be in order if you
don't mind building your own open-wire matching sections of
various impedances (change the impedance by changing the
spacing between the wires). Adds to the fun, right?

I have a 40 meter dipole fed by 50 feet of RG 8x coax. Appear to be no shorts and coax is new. Is supposedly resonant at 7.116 mhz. Transmit at 7.116

I get an infinite swr. According to Reg Edwards dipole 1 program I should have ca 1.45 swr. (swr v 50 ohms due to Zin 1.32 to 1. VSWR on feeder 1.45 to 1. efficiency 60.3%) Am I reading this wrong?

With use of a tuner I can get it down to 1.25 to 1

What could cause this very high swr? open line?

I like the "potato-cannon," (sometimes called a Spud Gun) idea too. Do a search on the web using one of the search engines such as AltaVista, and you will get lots of ideas. For me at least, it works better than anything else I ever tried. I'm getting too old to fool around climbing those damned trees anyway! A good search will give you plenty of ideas on how to build one. Should be able to build one that will work just fine for less than $25.00 if all the parts are purchsed new - much less if you're a scrounge like me.

Just be careful...

1) Although ATF doesn't consider a Spud Gun to be a weapon, some jurisdictions might frown on their use, or simply outlaw them altogether.

2) Though not considered a weapon, you should exercise at least as much care (firearm safety and common sense rules) as if it were a weapon. One day I shot mine just as a demonstration to a fellow ham where I work (ARRL VEC). With no messenger line attached to the potato, it went sailing at least a couple hundred feet into the air and traveled perhaps 500 or 600 feet before landing!

3) Don't get carried away with the Spud Gun. You might have more fun with it that you will putting up the antenna.

73, BE CAREFUL, and enjoy,

Wayne, W1KI

Slowly, I am assembling the complete set of accessories for my Millen 90651 GDO. Now I am especially looking for the 90751 Tone Modulator. Small 1-5/16" square box 2-3/4" tall with a 1/4" phone plug sticking out of one end.

Two other items on my want list are the Millen Balun #46672, and the 90671 SWR bridge. Any and all leads appreciated.

Ray,

Generally if you buy a tract home put up in the last 20 years, you will have some kind of antenna restriction. These are not ordinances, but Covenants, Codes and Restrictions (CC&Rs) that run with the properties. Doesn't matter if the area is incorporated or not. The big factor in the commute is time, not distance; 60 miles might take four hours. You might be able to find somewhere out in the Central Valley that would meet your requirements. I hear they run a train into San Jose area from there now.

1990. Can I hide an antenna in hedges?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-16 04:01:27 UTC
From: ve3tmt <ve3tmt@rac.ca>
Message-ID: <3d0J7.37225$wd1.2868784@news20.bellglobal.com>
Source record: 154743

Living in an apartment complex certainly has it's drawbacks. No outside antennas are permitted at all, even my satellite dish had to come down. I have tried using small loops for HF, and hamsticks, but I can't put them outside, and my shack is in the basement. I had an idea and was looking for comments. There is a long hedge that runs the length of the backyards (including mine) that I can reach with coax. Would it be practical to hide a random length of wire in the hedge and feed it with coax buried just below the ground. Although the hedges shed their leaves in winter, I think it will still be hard to spot. I could use clear insulated 12 or 14 gauge speaker wire. I would like to operate 40-10m, and some of 75 if possible. My FT900 has a built in tuner, so I am wondering the following:

1. Is there a magical length of wire I should use for the radiator to get those bands?
2. What is the best method of feeding the antenna? Should I use a balun or choke?
3. What about a counterpoise? I really can't run the wire in both directions (such as a dipole), so my ground may consist of a length of wire dangling at the feedpoint. Or is a ground rod better?
4. I realize at about 4 feet above ground it won't be even a good antenna, but it will get me on the air, what type of RFI complaints should I expect? I do have a low pass filter in line.
5. Is there one coax better than another for underground installation?

I have tried all kinds of other setups, and none really seem to work out. Please don't suggest moving!! If I could I would. If this idea seems feasable, it may be a weekend project.

Thanks for all your ideas,

Max ve3tmt@rac.ca

Speaking from experience, one of the coils in the tuner may be damaged.
I've overheated mine (several times, several years ago), and that's the
result. It doesn't have to smoke or char. Very slight discoloration of
the coil toroid means it is no good. Replace it if you find one.

Mike Powell wrote:
"(U.S. money) It`s also imprinted with Masonic symbols too, I believe. Any reason for this?"

Yes and no. Many of the founding fathers were members of the masonic organization, but most of the symbols are found elsewhere, too.

The symbols you are probably referring to are are on the reverse side of the "Great Seal of the United States" and this appears on the reverse side of a dollar bill. There is a pyramid with an eye above it.

Sovereigns have from ancient times authenticated issues with the imprint of an official seal. Kings used their rings to make an impression in sealing wax. So, the U.S. during its formation decided it needed an official seal as one of its first acquisitions. A committee of prominent founders was appointed to pick a design for the seal. They in turn went out for bids from leading artists. These submitted designs, as a nice reward was promised the winner. The committee negotiated slight changes with the artist submitting the design they liked best and awarded him the prize. That original design with few subsequent changes is the same as that appearing on the dollar today.

The decoration of the Great Seal and the money it appears on is a result of "The tyranny of the first draft". Had anyone wanted to change those symbols, it would have and still will require an act of congress.

Significance of the symbols, just like the beauty of these decorations is probably in the eye of the beholder. The real significance is the denomination printed on the bill and the statement: "This note is legal tender for all debts, public and private.".

Best regards, Richard Harrison, KB5WZI

<snip>
The much anticipated announcement of Pitcairn's induction into the
IARU was delayed. The vote will be tallied first thing today and an
announcement is expected. Meanwhile the VP6 Ducie Island team left
Mangareva, Gambier Islands shortly after sunrise yesterday. The team
was last heard operating maritime mobile around 1800Z on Thursday.
They have not shown up for any of their schedules, as of press time.
Tom Christian, VP6TC, reported there were several small earthquakes
felt on Pitcairn yesterday. In Fiji yesterday another earthquake was
reported at 0813Z measuring 4.6 on the Richter scale. The team is
expected at Pitcairn Island around sunrise local time. One station
reported working Mike, K9AJ/FO0MIC, who supposedly said the team would
be up and active on Sunday or Monday. Let's hope this is incorrect
and the team does show up around mid Saturday (Z) as was reported
yesterday.

Max,
The quick and dirty answer would be to move. But, I guess tht's not
too practical. So...
1. Magic lengths. An end fed 1/2 wave is probably going to have too
high an impedance for your tuner. So try a 1/4 wave length, like a 1/4
wave vertical, but 'laying down'. Make it for 40 meters (80 meters if
you have the room).
2. Balun or choke? I think I'd try the choke, probably more effective
than a balun because the impedance won't be the same on all bands.
3. Counterpoise/ground rod. Or maybe radials? Several as long as the
radiator, buried (more is better). Ground rod in addition wouldn't hurt
either.
4. Will you have any RFI? Who knows? But the safe bet would be that
you will. Still no way of knowing how much without trying it. Use the
LP filter!
5. There are several types of coaxial cable jackets/insulations, a
number of them made for burial. I don't remember the designators off
hand, but check in a catalog or two, or with the 'Wire Man' on the
internet.
You already know that this won't make the 'best' antenna in the
world, so don't be too disapointed with how it might work. Although, it
might suprize you (and me too)...

Jerry,
I don't think your reading it wrong, I think there's something else that's the problem. An infinite SWR just isn't reasonable for even a badly tuned dipole. I think I'd take another look at all the connections, PL-259's, and feed point. There's either an 'open' or a 'short' somewhere...

Source record: 154752

Doc is correct.

You must place -some- electrons in the circuit to see where it resonates, and what your return loss is (SWR, if you wish). The only difference is what you use to inject a signal into the antenna or feedline.

1. You can reduce the output power of your radio down to the operating threshold of your SWR meter, and service your antenna, tx line, etc that way. If your radio output can't be adjusted down, or has fixed incremental steps like modern tranceivers, you might have to get an attenuator or 'pad' to step down your power even further. Variable pads exist, but they're expensive and usually can't handle a lot of power. FYI pad specifications are usually in dB, so you'll need to know your radio's lowest output power, and the desired attenuated value beforehand (dB is a power ratio).
2. You can buy an antenna analyzer from MFJ or a similar device online. Since you aren't specifying where you intend to operate, I can't say whether anyone makes an antenna analyzer in the frequency range you'll be using. The antenna analyzer displays the dip point for you, and should automatically update as you change the resonance point of your antenna. I'm more familiar with the FDR meter (see below), so I can't speak from hands-on experience with MFJ's antenna analyzer. It looks like it should work.
3. If you have a lot of money, you can buy a Frequency Domain Reflectometer (used=$4500 and up). Anritsu makes a good one. This device will measure SWR, return loss (dB) or distance to fault (DTF) depending on how you set it up. It's the silver bullet you're looking for, unfortunately it's made of unobtainium. The primary advantage of an FDR meter is that it measures SWR over a band and displays the dip point, a major plus if you're tuning antennas. With an SWR meter, you'd have to take 2-3 measurements at different frequencies to estimate which way to tune, the FDR meter shows you the whole picture at once. One Anritsu model displays 5-1200 MHz at one shot, and can export the SWR measurement arrays to a PC through a data port. Nice. From my experience, you can -hear- the FDR meter, but it's a "blip" as it tunes past. It's such a low energy level that a few yards away and the signal's gone. Obviously the power level isn't harmful to us, and touching the device under test only changes the impedance. Warning-can hold you transfixed for hours playing around with random metallic objects as 'antennas'. Unfortunately, it'll be a while before we see FDR meters hanging in the checkout aisles in your local stuff-mart.

All these devices inject a small amount of RF into the circuit, albeit a tiny quantity.

Hope this answers your question.

First, check the basics. Are you feeding it where you're supposed to?

Is it grounded properly? If center-fed, are you using a balun? Are the radiators isolated at the ends?

Did you do a quick DC/ohmmeter check of your transmission line to detect opens & shorts?

How does your SWR read with a 50 ohm resistor across the feedline in place of the antenna?

From your description of the symptom, a tuner probably won't help you.

300 ohm twin lead is fine as long as it stays dry. Look for the
fattest wire diameter. That means a lot more than the foam. Not all
are equal. Some use real thin wire, some are a bit better. I have two
versions at the moment. Ones a foam type with pretty thin wire, and
the other is the harder stuff that has a bit thicker wire. It's the
better of the two. I think it was "radio shack" heavy duty type . The
other thin wire stuff I got at home depot. I use 300 ohm line to feed
my attic 40m dipole. "all band 40-10". I'm on it right now, as I'm in
the storm mode waiting for rain to come though. All my outside
antennas are grounded out right now as I'm paranoid about lightning.

Source record: 154755

I have a Yaesu FT-900 and a dipole that I built that will allow you to run 5 bands without any tuner other than the one built into your rig.

Antenna is 94' across the top, that's 47' each side of center. Its center fed with 41 feet of 450 ohm ladder line. At the end of the ladder line, connect it to a 1:1 balun, then 50 ohm coax to the rig. The one I'm currently running seems to do just fine without the balun. This antenna will not tune up on 21 MHZ. If you want to run that band, you'll have to run a small 1/4 wave piece of wire off of one side of the balun and it won't work very well. A better solution would be to do some experimenting with the 94' section. If that was also made from ladder line, maybe one strand of it could be shortened to a length that would work well on 21 mhz. This antenna works GREAT on 7.1, 14.2, 18.1, 24.9 and 28-29 Mhz where the swr is never more than 2:1 without any tuner. 3.56 mhz its about 7:1 so I don't use it much down there.

Let me know if you decide to try it and give us a report!

Source record: 154761

I've been using the Alpha Delta DXCC multiband dipole with excellent results. Its somewhere around 82' long and covers 80, 40, 20, 15 and 10. I considered adding more "legs" for the other bands, but instead I made a delta loop (51' of #14 wire in an equilateral triangle, flat side on top, with a 4:1 balun and that covers 17, 15 and even 12). The DSCC is only up about 40' and the bottom of the delta is about 25' up. Neither requires a huge lot and they're just strung between trees. I used the green flexweave wire for the delta and it is darn near invisible.

Both of these are tuned by the ICOM 775DSP internal tuner with no problems.

Source record: 154760

Another alternative I have is to form the radiating element in a rectangular pattern on my outside wall, using standoffs to keep it away from the brick. I can paint the standoffs to match the brick and use very thin wire for the antenna. This would be more proactical because I can start the square in the bottom corner where the coax exits the basement. Run it up the wall then down to the end of my unit, then back down again and secure it tight. I can manage 32' easily in this configuration. But again I have to feed it with coax. Ideas??

I appreciate all the advice I'm receiving and taking notes.

Thanks,

Max ve3tmt@rac.ca

Another problem that can arise when measuring impedance and SWR with a very low power source is interference from other in-band signals arriving at the antenna under test. Impedance and SWR information is basically determined from the ratio of the reflected signal arriving at the source to the source signal itself. In-band signals received by the antenna will be interpreted as reflected signals and can drastically affect the measurement. While this may not be a concern for most sites, it can be a real problem. When I used to measure impedance and SWR of HF antennas on-board Navy ships (at dockside) nearby active transmitters were always a problem. With a network analyzer (+20 dBm), you could watch the smith chart and SWR curves bounce all over the place.

From: asdfd <asdf@sdf.com>
Message-ID: <3BF51DEB.9B425816@sdf.com>
Source record: 154767

Hi,
I'm trying to design a four antenna phased array, this will allow me to send a signal in any direction. I'm new to antenna design, but I found EZNEC design software and found the phases which will point the array in 4 directions (good enough for me for now). The question then, how to set the phase ? One approach is to let the feed run through a switch which connects slightly different transmission lines, and the delay is related to distance. But then it was pointed out to me that a simple calculation of 1/4 wavelength doesn't work.
This is going to take some work to understand, so I'm trying this newsgroup. I could skip the theory if there were a design ready to go that I could duplicate. One problem, I'm working 433.92MHz.
The application is something like packet radio. And after this, I'm doing something called a convolutional code, which is complicated too :)

Jerry (new general) wrote:
"Is there a way to measure SWR, impedance, etc. without going on the air? A meter or something?"

An ohmmeter requires a battery to send a small current through a d-c resistance for measurement.

An r-f impedance bridge requires a small r-f signal through an impedance for measurement.

I would not consider applying a small signal generator to my r-f bridge "going on the air".

In-line ammeters, power meters, and bridges are designed to operate with "on the air" power.

Admittance and impedance bridges are designed to operate with a tiny signal input. A sensitive receiver used as a bridge detector enables measurement with a tiny signal.

Impedance of a load (the antenna) can fe measured. This can be done by using any number of 1/2-waves of transmission line to connect the bridge to the antenna. The impedance (Zo) of the transmission line can be found using the r-f bridge.

From measurements with the r-f bridge, the reflection coefficient and SWR can be calculated.

The answer to Jerry`s question is a qualified yes.

Best regards, Richard Harrison, KB5WZI

Neither the GAP nor the Cushcraft R8 or R6000 require radials. They do have a structure at the bottom of the antenna. The Gap Titan has a wire loop about 3 meters in diameter. The Cushcrafts have wire spokes about a meter long.

It is a good idea to run the coax straight down as far as you can before you turn it horizontal. That helps stop RF from getting on the coax and causing RFI. I had a lot of trrouble with that.

Neither antenna requires a ground. You only need a ground for lightning. protection. You ground the mast the antenna is mounted on. You can tape your coax to the ground wire for about a half meter just before the coax makes a turn. Then you "hope" the lightning jumps over to the ground wire before it travels down the coax to your shack. Not very scientific but it offers some protection.

Bob, K5QWG wrote:
"Could the swr be extrapolated from the measurements of a bridge?"

A bridge can tell you the load impedance. Knowing Zo and the load impedance you can calculate swr.

H.L. Gibson, G2BUP, says in "Test Equipment for the Radio Amateur" that the level of noise used as a bridge signal is 100 microvolts in a noise bridge presented in his book. That`s hardly "on the air" in my opinion.

Best regards, Richard Harrison, KB5WZI

Knowing them, I would doubt it very much. I fought them on the satellite dish issue and they threatened me with eviction. They also made all the other tenants remove theirs. I wondered about the flag pole idea, how can they threaten me for flying a Canadian flag in my yard. I'm sure the newspapers would love to hear about that.

Hi Richard:

For the work I was doing I had to measure over a full HF sub-band such as 2 - 6 MHz, 4 - 12 MHz or 10 - 30 MHz and record the impedance data for subsequent matching network design. With the analyzer it was easy to measure and record the data over the entire band. However, the front end of the analyzer was sweep sampling the entire band and the interfering signals were "measured" as well. Every measuring device has pros and cons.

Thanks,

Steve VE9SRB

Max,
I think the 'loop' would stand a better chance of working for you
than the 'hedge' antenna! For multi-band use a loop as large as you can
possibly make it is the way to go. The impedance/SWR isn't going to be
good on any band, so a tuner would be necessary. If you can use two
walls, making the total length even larger, you might get close to a
full wavelength on some band. Still not the 'best' by any means but
since it's higher than 4 feet it almost has to be better than the hedge
(LOL).
Now the 'down' side. Count on RFI, and maybe not just a little bit.
An antenna closer to the other electronic equipment in the house is
going to be more of a problem than an antenna further away. Distance
heals all RFI...
'Doc

Always use ear and eye protection and gloves when using this type of device.

Observe local rules so you do not get in trouble !

Just to clear things up: my radiating element is a Diamond mobile
antenna.But since I want to use it as a GP,I don't have the car roof as a
counterpoise,so I need the radial length amd diameter.But I assume the 51,25
cm will also work for the Diamond

I have just put up a Cushcraft R7 vertical antenna. It is a good performer, but I am concerned about its ability to stand up in anything more than a light wind.

I am trying to think of a way to make the antenna more rigid -- perhaps by inserting bamboo poles inside the hollow tubing elements, or some other means if anyone has a good suggestion.

One consideration was to fill the elements with an expanding foam product. I have heard of such a product but don't know where to begin looking for it -- can someone help?

Any suggestions welcomed. Thanks in advance for any ideas or assistance you can render.

It should be fine. My brass rod stock groundplane does great, and
I've noticed since finishing it that my four radials have at least
three different lengths - though within 2" of th right length.

I hear you on the grounding!

My 300 ohm comes to a large open frame industrial relay (30 amp contacts).
When station power is "on" the relay connects the antenna to the tuner.
When station power is off the relay connects the antenna to a beefy ground
line run to my station ground.

From the relay to the tuner I use home made parallel line. #18 wire and
"plastic staples" meant for electric wire. Pull the nails out of the
staples, enlarge hole if need be, and thread conductors through nail holes.
It makes a nice flexible line, not 300 ohms but useful. It is NOT my idea,
I copied out of some antenna article.

Yes when buying 300 ohm line you do need to watch the wire gauge.

My feed line is almost all verticle, so I don't worry about increased loss
due to water on the line.

The air cannon that is simplest to build uses a valve available at the home and yard improvement store.

I think some one got wise to the use and risk as the current production of valves open too slowly to be used in an air cannon.

There is a simple fix for that that is posted on a ZL's page along with the theory. I also have the information on how to speed up the valve using slightly different materials.

Steve, VE9SRB wrote:
"Every measuring device has pros and cons."

Very true. We were always adjusting antenna tuning on a frequency different from any in use at the moment. We did have one swept-frequency application at the station. It was a back-scatter ionosphere sounder used with our directional antennas. We could determine the maximum usable frequency. This had little practical value for operations at the measurement time. Broadcast schedules had to be made and published a month in advance. H-F relay frequencies to deliver programs to the transmitters were just as well determined by trial and error at the instant. We used triple diversity reception (TDR) and were constantly selecting the best frequency by adding a frequency to replace a band or a frequency which was disappearing. We used an h-f order-wire transmitter to notify the sending end which bands to add or cancel in their repertoire. The "sky checker" was just for science.

>Best regards, Richard Harrison, KB5WZI

Hi Richard,

100 microvolts is barely a specification. Used in the bridge? Does that mean it splits evenly between load and reference? Is this 100 microvolts into an equivalent load of 50 Ohms? Other?

Is this 100 microvolts in a 1/SQRT(1Hz) bandwidth? Is this 100 microvolts wideband? The difference between these two is astronomical.

Anyway you look at it, the amount of power applied to the antenna for the purpose of determining SWR - by most means - must exceed that power already exciting the structure. As an antenna resides in the real world of saturated airwaves, finding 100 microvolts at some opportunistic frequency may well obscure this bridge's capacity to measure Z. Most noise bridges specify this proviso in the fine print in the appendices.

The quality of measurement is always found in the signal to noise ratio. 3:1 is considered the least useful except under the best of circumstances; and 10:1 is preferred.

Perhaps I should pursue the QRP aspect of the hobby!
I guess I could always run the coax out to the car, but I don't think they would appreciate me digging up the parking lot to bury the coax!

They are in the process of replacing all the upper patios around the building, and I have seen the finished work. There are a couple of new supports on the wall, perhaps I can string some patio lights up and "hide" the antenna wire in with them.
When opportunity knocks...

Irv, VE6BP wrote:
"I am trying to think of a way to make the antenna more rigid--"

Rigidity comes from fibers in the outside of a structure. Wide-flange beams and tubes are relatively stiff. It may be more rewarding to closely fit and attach something to the outside of an element than to insert something inside.

i dont think you have to much to worry about they have been tested and withstand a good deal of wind but you could always guy it using dacron rope
i wouldnt use bamboo cause it could suck up mosture and change the SWR of the antenna good luck

"100 microvolts is barely a specification."

That`s right. It is only a small number. I took it to be the noise output measured with a wideband voltmeter of the "signal" applied across a noise bridge. As such, it splits equally between the aerial and a balancing load.

Since this 100 microvolts is composed of a wide band of frequencies, the signal at any particular frequency is small indeed.

Someone gave me an old '40's-looking B&W balun. It consists of:

- 2x B&W 3975 ceramic-based coils;
- a B&W 3977 aluminum base, w/coax connector thru one end & 2 feedthrough terminals thru other; this mounts the abv coils parallel at 90 deg;
- coils are 2 1/2" dia, parallel-wound (double), 22 turns each (i.e., 44 single wire turns), spaced abt 1/16", abt #22 silvered wire, 4 9/16 long;
- each line leg is connected series thru both coil units to the other leg in one direction, and tapped through just one of them to the feed-throughs in the other direction.

My sense is that this is a 1:4 xmfr not good below 40M (due winding lengths? I read somewhere that the winding has to be abt 1/4 wavelength at the lowest band?), but I'd like a more knowledgeable assessment B4 I frig with it. I did clean it up and straighten the mashed windings (you know how it goes with this stuff).

Side observation: why is it that B&W used that horrid once-soft poly strip for coil supports that shrinks & breaks over time (rhetorical), and does anyone have a favorite repair method for this common problem? I have even seen this material break the ceramic base by shrinking with age (on other coils).

Thx in advance. :-)

Do a little research on Richard Fenwick and ESI. He did this in the sixties, marketed on HF in the seventies, military has it in use now for UHF.

Bob Alexander repeated Dick's work and wrote it up in one of the ARRL ANTENNA COMPENDIUM series books.

Hope you aren't supporting the RFID programs - you're playing in ham spectrum.
Hope you're aware the use is being challenged and unlicensed use is hopefully to be denied.

bests,

Hi,
from the W in your callsign I assume you are american, however I am not.
This political situation sounds intriguing, however in my country I can use
this frequency without limits for non-continuous transmission under a
certain power (as far as I know).
I am also not involved in ham radio in any way, but I thought this group
might be a place to help. The antenna I am making should be for portable
use, when someone talked about harnesses and so on, it sounded big. I'm
looking at maybe 1/8wavelength size or 8.5cm/3.3 inches.
I found your reference to ARRL, and I read about the RFID debate, however I
am just an electronics hobbyist and if I use this radio, it will be for a
few minutes every once in a blue moon when I feel like experimenting. I
guess that would make me on your side (?) if I were in your country :)
Thanks for your help.

Dennis, K4OXG wrote:
"I wouldn`t use bamboo cause it could suck up moisture and change the SWR of the antenna."

Irv was considering inserting bamboo inside the tubing. That might work to stiffen the tubing.

All radiation is from the outer surface of the tubing. Like charges repel, so they disperse to exterior surfaces. The inside diameter is far less than 1/2-wavelength, so r-f doesn`t travel through the tubing as a waveguide. The frequency is far below the cut-off frequency. Nothing that goes on inside the tubing has direct electrical effect upon the antenna.

Bamboo in there could be wet, dry, or in-between and you would never know the difference.

Best regards, Richard Harrison, KB5WZI

I have a Kenwood 570 with an auto-tuner. According to Kenwood, it will only tune from about 30 to 90 ohms. An 80mtr dipole used for all 9 hf bands will have a wide swing in impedance from several ohms to perhaps close to 1,000. That is well beyond the range of my auto tuner to handle, so I would have to say that you will need a manual transmatch, just as I am using on my 120 ft dipole.

He could use a modeling program. Some common antennas are already in them , and is easy to scale. If looking for a certain antenna, just do a search on yahoo or whatever. Sometimes I think no one ever uses search engines judging by some requests I see. I'll do a fast search and the links usually floodeth forth..I replied to another guy asking about marine stuff, and it turns out the post was from 1997. The perils of google...If a header matches an old subject, it shows them all. Sometimes I forget to look at the date. I'd use my ISP news server, but it's feed is so slow it's pitiful. Google is actually faster, and thats pathetic.. I need a new ISP, but I'm too lazy to switch everything.. MK

2061. Re: What is best kind of rope for dipole mounting?

I'm using polester rope for my tree mounted dipoles, only because that's what the package recommended. One end is mounted solid and the other goes thru a 4" clothesline pulley and counter weight. I used 30lb fishing line with a bow & arrow with a golf ball on the tip It worked great and was extremely accurate, but the rope squirming on the tree branch (over time) will cut into it, pinch and may become impossible to remove...I've had it happen. Good Luck

Foam doesn't have much stiffness against bending, but most kinds of wood do. Bamboo is OK if it's the right size to support the inside of the tube. It doesn't need to be a precise fit, but also not so loose that the tube has to bend a long way before it gets any support from the wood.

Since bamboo doesn't come in specified outside diameters, it may be better to use square hardwood, with the edges planed down to let the wood slip inside the tube. Do NOT make the wood a solid jam fit, because it will swell outdoors and may even split the tube. A quite loose slide fit is all you need.

If you stiffen the tube, ALWAYS go all the way down to the bottom. If you only stiffen it part-way up, it will break just below the stiffening because you've concentrated all the bending stress at that point. If you avoid that mistake, the point of maximum bending stress moves to just above the stiffening, where the tube is unsupported again. That can mean that the element still breaks, but at a new place.

It's always best to look at how the whole thing bends in a breeze, and notice where the stress tends to be concentrated. Then stiffen it past that point, and some way above. The ideal arrangement is that the bending stress is absorbed gradually all the way up the element, rather than being concentrated at any one point. This probably makes a well-designed element look quite wavy, so don't assume that the element needs stiffening just because it moves about in the wind.

2063. stub-phased collinear question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-16 22:35:42 UTC
From: tom_bruhns@agilent.com
Message-ID: <3832adca.0111161435.355b2e21@posting.google.com>
Source record: 154716

Hi all,

Anyone have any comments about the maximum practical length of a stub-phased collinear? I'm thinking about the sort of antenna that's a string of resonant half-waves end to end, with a shorted quarter wave stub of open-wire line across each pair of adjacent ends, the stubs sticking out perpendicular to the axis of the antenna. I can imagine that to keep things properly phased all the way along a couple dozen elements might be a bit tricky, and the current magnitude may not stay very constant along the array (from element center to element center, for instance), but wonder if anyone has played with this sort of antenna to get a feel for things like this.

Cheers,
Tom

Perhaps you might consider a terminated end fed wire. I am not capable of designing it for you, but it basically is fed at one end, while the opposite end is terminated into an appropriate resistor (ie dummy load), which dictates the impedance for the antenna under all operating conditions.

Hi Tom,
There will be, I believe, diminshing current in each successive element. But I think I would change each element from a 1/2 wave to a 3/4 wave w/ max current in the middle.
This amounts to 1/8 wave out of phase at each end of each radiator. The advantage is that it increases the distance between current lopps thereby increasing gain AND each phasing stub is now 1/2 as long. The bottom radiator can of course end up at a current max for resonance.

Source record: 154622

Have you considered using the same size antenna as a vertical dipole, thus eliminating the radials ?? I believe 33ft is the recommended length to maintain low angle radiation on 10 mtrs. and your proposed height above ground is a plus. Running the feedline away at a right angle is a bit of a bother, but not so much for my 2nd floor shack. All you'll need is a tuner and ladderline. Good Luck...Doug / WB3EGX

2070. Re: open wire/ladder line feed question

Source record: 154623

I would suggest only putting up an 80 mtr dipole ....feed it with ladderline, and use it for "everything" by running it thru a tuner. If your rig has an auto tuner, it won't work with ladderline. I am using 300 ohm outdoor TV feedline from Radio Shack. It's not the best, but it will handle about 500 watts and get you on the air.
Good Luck...Doug / WB3EGX

As Dale stated, the current diminishes quickly along the length of the array in a series fed design. Once you get past 5 - 8 elements, you start to run out of steam quickly.

One of the most common phasing mechanisms used is a phasing coil as seen on many automobile cell phone antennas. The phasing throughout the array is not that difficult to maintain. Getting the correct coil dimensions is a tricky process. One problem we encountered in one array design was the wire length stretching by as much as 10%+ as you wound it into a coil.

Source record: 154629

Sounds like an air-core balun that was popular back in the 50's era.
Heathkit sold one like that to go with the DX-100, etc.

It can be wired at the terminals for either 1:1 or 4:1 transformation.
Please don't ask for the details since I have long forgotten, but surely it
is well documented in the handbooks, etc.

As I recall, the Heathkit unit was longer, about 8 inches, so you might be
right about it being a 40-meter and up affair.

It should be easy to get some idea of how it works by hooking a 50 ohm
resistor to the "balanced output" terminals and seeing what the input looks
like with an impedance meter (antenna analyzer) at various frequencies.
Repeat using 200 or 300 ohms.

These were basically used to transform 75-ohm coax to 300-ohm Twinlead,
hence the 4:1 configuration.

Interesting piece of gear . . .

Side observation: when you get as old as that balun, you will have shrunk a
little yourself! <:}

> stand up in anything more than a light wind.

(cut for brevity which for me is unusual)

Thanks for the replies guys. I've decided upon the
following ---

1. I'll leave it up as is. Doc, W5LZ and Dennis, K4OXG
convinced me that nothing additional should be required.
This is like the first tower I put up, and lost some sleep
wondering if it would stand up overnight. There are
sufficient R7s and similar which, if wind were a problem, we
would have heard much more.

2. If something does happen, and something folds or leans
too far, I will brace it with clamps and aluminum
angle stock (as suggsted by Doug, WB3EGX), and Richard
KB5WZI also suggested a rigid attachment.

3. Thanks, Ian, G3SEK who suggested square hardwood stock
inside, and also pointed out that any bracing should go all
the way to the bottom so as not to make
the lower part a fulcrum for aluminum (aluminium for you
Ian) fatigue.

4. If you will pardon the pun, I think Dennis, K$OXG was a
bit "bamboo"zled on what happens inside the tubing, but
Richard took care of that matter.

5. Thanks again, and now -- back to DX'ing! 73

My suggestion is that you pop for a copy of the ARRL Antenna Book and
start at page one and very carefully digest the whole tome. If done
properly you'll be answering your own antenna questions.

Seems to be "small Potatoes" to me- I saw a CB antenna in a store
earlier this year that had the label "Guaranteed to handle 3000 Watts".
It WAS nicely Chrome plated, and had tubing in the coil.

Not if you choose the proper length of ladder-line for each band.
My 80m dipole has an SWR of less than 1.6:1 on *ALL* HF bands
using *NO* antenna tuner.

>
> What could cause this very high swr? open line?

I think the antenna may be resonant at some frequency far enough distant from the intended that SWR is high enough that it looks like it's infinite. I base this mainly on the fact that you can tune the antenna and get it to 1.25 to 1. If it was shorted or open that shouldn't be happening, unless you converted it to a Marconi by shorting the feedline and feeding the whole affair as a single wire against ground.

One thing you soon learn when building amateur HF antennas is that the surrounding environment has a lot to do with the results and will cause considerable shifts in resonant frequency under the right conditions. The formula used to measure the dipole elements is the *free space* formula, and most hams rarely mount an antenna in anything like free space. If you have it mounted low and/or near any object, particularily metal, the resonant frequency can/will change considerably. The closer the object the more the effect.

After you check out your feedline and coax connectors for problems and still haven't resolved the situation you can either run the transmitter down in frequency checking SWR to see if it begins to come into range, or you can trim the elements and recheck. Mostly you will get LOWER frequency shifts since the added capacity to ground or surrounding objects will lower the resonant frequency.

Here is where one of the antenna analyzers comes in very handy. It will make short work of resolving where your antenna is resonant. It will sometimes surprise you how far off it is.

> Irv VE6BP

Filling tubing with foam will make it stiffer, as long as it doesn't
bend too much and break down the foam.

Having spent some time stiffing a telescope mount with this technique,
I can offer the following:

Don't bother trying the "foam in a can" stuff sold for home insulation. It
does not set up well in tubing (actually, it makes a hell of a mess).

The stuff that works is sold as a 2 part kit and makes closed cell foam.
It cost me about $40 for the smallest kit the dealer sold (enough for a
WHOLE lot of antennas). I got mine at a local plastics supplier; no idea
if such exists in VE land.

It contains some nasty chemicals and is messy to work with; wear protective
clothing to keep it off your skin with plenty of fresh air.

Cleaning up the ends of the element pieces so you will be able to
disassemble or adjust the length will be a challenge.

I wouldn't bother. It would be easier to put up some nylon guys if the
winds are particularly strong in your area. The winds gust to 80+ Mph
here during Santa Ana season and didn't do anything to the nylon guyed
4BTV with 80M trap on top I had up for about 10 years.

If you are going to run a random wire, and if there are trees or other supports available higher than a hedge, why not try very fine enameled magnet wire, say 26-30 ga.? Almost impossible to see, even when you know its there. Or, if you have roof access, and the roof doesn't have that much metal in it, try laying a random wire/dipole/full loop on top of the roof, out of sight, out of mind. As for a ground, I have been in seriously restricted apartment QTHs before, and have found that artificial ground devices work quite well, enough to allow the rig to load the antenna (a 60-70' length of #26 mag wire running just above [<12"] the roof [itself at about 15'], and touching it in some places), and to make lots of coast to coast contacts, >S5, on 40 SSB with 50W, and enough EU and SA/AU/NZ DX (on the higher bands) to keep me reasonably contented. I used a Ten Tec (www.tentec.com) artificial counterpoise, which comes in a kit for about $60 US. If you are inclined, you can homebrew such a gadget for a lot less, as all it is is a coil and cap and a RF ammeter. Best of success to you, and 73 de

hello tonny
i was going to do this very same thing using 4 10 ele quads for 2 meters and the info i got was to space them 10 feet apart in both planes
keep in mind too that you will need to use a nonmetalic Hframe to limit interaction with the quads
good luck and send me a photo of the array when you get it in the air would love to see it

See chapter 16, "Mobile and Maritime Antennas", in the 19th edition of the "ARRL Antenna Book".

There is a current thread in this newsgroup: "vhf". See it for several very good links to information on antennas good for yachts.

At h-f, vertical polarization is advantageous over a highly conductive surface such as sea water.

Ron, believe the makers of the 'Outbacker' mobile antennas
produce a salt water version of their tapped helical antennas.
In fact, they will custom make it for your particulare freq.
bands (if you are looking for marine freq's rather than amateur).
Just contact the US distributor (belive he is in Tenn.) and he
will put in special order for you (only takes a couple of weeks,
even tho the manufacturer is in Australia)

Max, since you can run a coax outside, is it possible to
reach your car? If you can do this, put a screwdriver
antenna on the car and besides the coax also remote the
motor control to your basement ham shack. I did this and
it worked just fine. Used three (3) 25' heavy gauge zip
extension cords for the motor contol (probably could use this
method for 100' or more). What is neat about using extension
cords is the ease in disconnecting when you need to drive away.
If you can do this, buy the High Sierra screwdriver (it comes
complete with stinger & control head and is very well
contructed). I currently have a screwdriver antenna by a
different manufacturer.

I am older than the balun, have grown nor shrunk, and don't need as tight a match as it does. Would like to find out specifically what the unit is if any may know or recognize it.

An "End Fed Zepp" is the antenna used by the zeppelin air ships.
It is a *single*frequency/band antenna. It is 1/2WL long fed by
1/4WL of open-wire line. A husky 1:1 choke would probably be
best as the currents in the open-wire line are unbalanced and
feedline radiation/RF-in-the-shack is a common result. The EFZ
was not meant to be an all-band antenna but some hams use it
that way in which case the feedpoint impedance is all over
the place, sometimes low, sometimes high, and most often
reactive. An EFZ is hard to tame for all-HF-band operation.

Marvin,
Yes, the feedline and antenna need to be particular lengths according to the frequency in use. If you use a balun (if the tuner doesn't already have one), I'd use a 1:1. Personally, I wouldn't use a balun, I think a 'coaxial choke' would work 'better' for you.
If the tuner you plan to use is an auto-tuner one built into the radio, I don't think your going to like the results. The 'auto-tuners' have a fairly narrow range of matching ability, and if you plan to use the end fed Zep for an 'all-band' antenna, I think you'll have problems.
But, good luck...
'Doc

Ron,
Not a simple subject or project! 'Back stays' and non-metalic masts
are two of the more common places to put antennas, and there are a
number of others. I'd suggest speaking with the commercial people who
do this, unless the antenna would be strictly for recreational use. If
the antenna is for 'serious' use, meaning you may have to depend on it,
I think I'd want a 'serious' installation...
'Doc

2113. CB truck antenna grounding.

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-17 21:15:06 UTC
From: Michal K <k7michal@home.com>
Message-ID: <B81C3B8F.370B%k7michal@home.com>
Source record: 154666

Hello.

If anyone can grant me some advice or suggest an idea I would be greatful.

My friend has a CB that outputs about 50 Watts or so (I know it's illegel), and an appopriately thick antenna on the front left mirror of the truck. He has been complaining that his voice sounds too bassy on the Rx'ing end. The antenna is properly matched.

When he took it to the shop, the tech said that the CB is fine and that the problem is probably poor grounding.

For this I decided to add four radials connected to ground, each is about 25 to 30 cm (11") at 45 degrees.

I realize that the radials should be at least 1/4 lenght (102") but that is not too practical for a truck.

If anyone knows if there is a good and efficant way to ground a truck antenna or if my idea might do the trick can you please let me know.

Thank you for your precious time.

2114. More bullshit from Cohen

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-17 21:18:01 UTC
From: chirp@fractennae.com
Message-ID: <9t6k69joi1@news.netmar.com>
Source record: 154667

"Update: Unauthorized copyright material has been removed at Fractal's
request
and the firm has requested more information in its assessment of the extent
of
further IP infringement..."

http://www.fractenna.com/nca_news_02.html

Admitted Cohen: "Not so long ago, the disruptive technology of fractal antennas couldn't be given away. Now we see the technology catching on because of its distinct advantages. Attaching tiny etched fractal antennas to bugs shows they can be easily made and work where other antennas can't. But the question that needs to be asked is: 'should they `bee' used where others can't?"

Cohen added: "Some bugs, such as moths, actually have evolved fractal 'antennae', but these are sensing organs and not wireless aerials. Adding (wireless) fractal antenna to bugs sounds a bit exotic for our tastes and is not an authorized application of our firm's technology: in six years under a corporate banner, we have yet to receive a request from a beekeeper and we didn't know that bees were under the purview of the Navy. Shouldn't it be the Air Force? In any case, anyone wishing to apply our technology in such a biological frame will have to present compelling reasons before we would even consider it. To us it looks like an attempt to open Pandora's Box."

Cohen notes that the firm has always encouraged other scientists to experiment with fractal antennas. "However", says Cohen, "when applications are done by others, without any effort to procure a license, that may constitute patent infringement and a deliberate effort to ignore our intellectual property."

Cohen was clear to stress that the web-disseminated Navy report also contains unattributed findings, and unauthorized use of copyrighted material held by the firm. " It's still a fractal antenna whether it's on a PDA, a wireless water meter, or an electronically souped-up June bug, and care must be exercised to avoid applying our technology and/or using our copyrights without permission or compensation. We'll put a bug in their ear, and a bee in their bonnet", assured Cohen, "but it's up to society to judge whether we really need bugs with fractal antennas on them--at least when they're not born with them".

> meters in diameter. The Cushcrafts have wire spokes about a meter long.

Two different animals though. The cushcrafts are 1/2 wave designs, and
the "spokes" are for decoupling. These really will work ok without
radials. But the GAP structure is a counterpoise of sorts, and the GAP
is not a 1/2 wave design. The GAP really needs radials in order to
live up to it's expectations despite all their "no radial" jibber
jabber in the ad's. The counterpoise they use is a poor replacement
for radials. It will really suffer on the low bands. On the high
bands, I suspect the cushcraft 1/2 wave designs would eat the gap for
lunch on 20-10 meters. Probably 40m also. Don't know about the
cushcrafts on 80m. I know the gaps aren't very good on 80 as they are
normally set up. I doubt the cushcrafts would set the world on fire on
that band either. I suspect regional coverage on either one would be
lousy compared to any kind of dipole. Might work fair on long haul
stuff if the losses don't eat you up.
>

You really want to to go all the way to the ground at the mast base
before going to the shack.
>
> Neither antenna requires a ground. You only need a ground for lightning.

> coax to the ground wire for about a half meter just before the coax makes a
> turn. Then you "hope" the lightning jumps over to the ground wire before it
> travels down the coax to your shack. Not very scientific but it offers some
> protection.

You want to run the coax all the way down to ground at the mast. Then
go off to the shack at ground level. If the coax is not snubbed to
ground level, but instead is routed to the shack while hanging in the
air, that can eat your lunch big time. Hoping a high resistance gap
will arc over is asking for huge trouble. It may well arc over, but
with a high resistance connection which will fry something. Having the
supporting mast very well grounded is 75% of the battle. You would
rather it direct the strike to ground rather than the coax. Never rely
on coax feedline to be a lightning return. You want the mast to do
that job. But you do have to consider currents on the feedline though.

Myself, I don't feel comfortable leaving any antennas hooked up during storms without advanced lightning protection. So I ground my coaxs outside during storms. I am using no suppressors here. MK

Michal;
The problem is not in the antenna. It has no effect on the audio portion
of the signal, that is all done by the mike and the audio processor in
the radio. Have the radio shop check the radio for the proper values. If
the signal is over modulated the station receiving the signal will get a
distorted audio.
If the antenna is mounted to the truck cab in an approved manner you
should not need to have any radials. The cab acts as the radials.

Dave Nagel WD9BDZ

btw: Go to another radio shop. The one you went to sounds like they
don't know what they are doing.

I ran a similar Cushcraft, an r-5, and never had a wind problem. I had it attached to a good, stiff mount, 1-1/5" plumbing pipe, held to the side of the house with RS metal straps. The antenna never gave me a bit of concern, even on the windy Gulf Coast. My neighbor had an r-7, also well mounted, and it did fine. If the mount is good, the antenna will take a hell of a wind. Don't screw it up by inserting a bunch or foam or whatever.

This newsgroup would be of more help if the old-wives, gurus and
ignorant 'do-gooders' did not give so many conflicting answers and
bicker amongst themselves.

How on earth is a genuine innocent enquirer to choose between them
all ? 'Multiple-choice' answers ?

It is not surprising novices are confused and display a little
irritation - only to be rewarded by insults.

Find another tech. While poor grounding of the radio antenna may indeed
affect the radio signal it won't have any affect at all on the voice
quality of the received signal.

That is determined primarily by the audio response of the microphone, the
modulating circuits, and the linearity or lack therof of the rf amplifying
circuits.

CB's often have "power" microphones that often add to the distortion by
overdriving the audio modulation circuits, as well as having poorly
designed (as well as illegal) rf amplifiers.

You might try listening to the radio with a stock microphone and without
the amplifier to see if it sounds normal without them.

Bob, VE7HS
"After first ascertaining that in the current recession the ratio between the blue-collar and the white-collar unemployed stands at one to one, the augurs produced a slight amendment of the general theory - among members of the lower classes, failure was a property of individuals; among members of the middle classes, failure was a property of the state. A poor man failed because he was lazy or stupid or criminal. A rich man failed because of a tax policy or the Clean Air Act. Nobody knew why this was so. It was a great mystery, like the mystery of existence, but nobody, at least nobody important, doubted the truth of so sublime a paradox." - Lewis Lapham

Bill:
The "peaked" CB's do usually + or -2 watts more & 40% louder modulation, basically. The BIG COIL antennas are rated for the BIG power, but VERY FEW people have even 1/10 of the power that the antennas aare rated at. Just more hype & lies from the Antenna companies, which you probably are familiar with, but maybe they just lie @ CB freqs.!

Have a look at the small plastic tubing you can buy at Home Depot.
Just yesterday I bought a 25 ft coil of clear polyethylene tubing
there - .250 OD x .170 ID. Cost about $1.70, I think. It is meant to
be a water line for an icemaker. Probably a snug fit in a 1/4 hole,
and if the element rod doesn't fit as-is, you could jam something like
a toothpick in next to the element to hold everything firmly

Howdy all,

Was in my local home depot today, picking up some stuff to do a few miscellaneous home repairs. As usual, I walk up and down the aisles looking for stuff that could be used for ham radio.

Well lo and behold, they now carry some aluminum tubes, both the square kinds and round tubes and sticks. These would be perfect for constructing some uhf/vhf antennas. Only thing I couldn't find was those black rubber grommets that hold the round tubes in place in the square tubes and keeps 'em from touching.

Anyone know where I might could find some, or what I might be able to use instead? With some of these it'd be real easy to start making some uhf/vhf antennas, and cheap too. Not to mention fun.

Thanks and 73's,

Robert / N4IXT

That's about what I do when I visit my daughter. The difference is that it is a wooden board fence so I tuck magnet wire down between the vertical boards and their horizontal stringers, and also I use two paralleled dipoles made from about 24 or 26 gauge magnet wire (you can use small wire as long as it isn't so fragile that it breaks) on 40 amd 20 meters. I tune it with the autotuner in the Kenwood TS570D (at a low power setting ~10 to 20 watts- initially to make sure it will handle it OK. It did.)
The dipoles are about 5 feet off the ground, but work out better than you might expect. I make plenty of contacts on 40 and 20, on SSB CW and digital modes. I try to keep the power down to 50 watts or so max, and less when less will suffice. No need to stir up the natives.

Since I don't have to hide the coax I just lay it on the lawn. I installed alligator clips on the coax antenna end so I just clip it to the feedpoint of the antenna and that makes for easy takedown. Since the feedpoint is the high current point you want to make sure you have good connections there, so be sure the clips get a goood grip.
The installation is so simple and easy I don't leave it in place, rather I remove it in a few minutes before I depart.
If your available mounting space is not long enough you can fold the ends of the longer dipole back toward the feedpoint to make it fit and it will still work. That will be easier in the hedge. I wind up folding back the half of the 40 meter dipole that is connected to the shield.
Getting out on 75 meters will be very iffy with any antenna this close to the ground. Not impossible, but it won't work well. And a 75 meter dipole is usually too long to fit.
The fence I used was away from the house, which is definitely a plus, and hopefully yours is away from the neighbors houses too. Someone else mentioned RFI. Running at reduced power will help keep your signal out of their goodies. Getting the antenna away from all houses as far as possible will also help reduce the TV birdies you always hear every 15,750 hz across HF. They do get to be tiresome to deal with.

Is there any set standard for a ham tower in a residential neighborhood or is that up to the local city/county to decide if and how much you can have. I would like a 50 to 100 foot self supporting tower.

2138. Re: How Tall Can Towers Be?

The FCC says 200 feet, unless you're near (within two miles, I think) an airport. Then you need to get with the FCC and the FAA to find out how tall your tower can be. Local ordinances may further restrict tower height, so check with your local authorities as well, to see if they have any standards regarding towers and amateur radio.

Kev,
The height of a tower is only limited by what you can pay for, how much property you have to put it on, local ordinances, and how close you are to an airport. Of any of the above, the $$$ and local ordinances will probably determine how high your tower is more than anything else.

Doc wrote:
"I`d suggest speaking with the commercial people who do this unless the antenna would be strictly for recreational use."

I got my 1st-class phone license in 1949 so I could legally make installations and repairs in boats, planes, and other commercial sites that I had long worked in. Thad Felton was a Ford dealer in this part of the world, and he gave me and one of the other operators at a radio station where I worked the job of installing the radio in his new yacht, a power boat. We, the operators, had made many previous intstallations before and made many more afterwards. We used a vertical whip on that yacht for h-f, and it tuned-up and worked well.

Antenna practice on yachts has changed little since then. The ARRL Antenna Book is not advising Radio Amateurs to use inferior practice. Professionals regularly use the Antenna Book as a reference. On a sail boat, a vertical wire supported by an insulated mast can work very well. A back stay has a large vertical component and it can work well too. Of course, the same vertical whip used on a power boat works on a sail boat too.

See:
Boat Antenna.com for the sort of maritime antennas you have likely already seen used on yachts for h-f SSB.

A description of the SSB 544-SS lists these features:
High performance Single Side Band antenna combines length with exceptional communication over the entire HF frequency range, with the use of a tuner.
-8` bottom section has a 1.5-in O.D. that tapers.
-8` top section has a 1-in tapered O.D..
-Stainless steel ferrules.
-High gloss urathane finish.
-Powerful brass radiators.
-Soldered connections.
-Side feed termination.
-Uses a center brace.
-Mounts on a standard 1-in 14 threaded swivel-mount.

Maximum input power: 1000 watts
Bandwidth: 2-30 MHz with tuner.

As I recall, a lot of the radios we used to install were from Apelco, a sometimes Raytheon company, and the antennas were mostly from Webster, another sometimes Raytheon company. Never had any serious problems with

either the radios or antennas. It seems from searching the web that Raytheon is not into providing the recreational boating market with these products at this time.

I used the same Apelco maritime radios in several Bolivian Chaco Jungle locations. Just hung a dipole as high as I could and in the clear if I could. I used RG-8 without any balun or other complication and the jungle installations all worked like champs and were trouble-free.

Best regards, Richard Harrison, KB5WZI

As it's common knowledge, the higher the antenna, the better. A dipole at 30 feet is good. Put that dipole on the roof of a three story apartment building is better. Not too sure I can acheive 30 feet above the roof, though. How much would one "guess-timate" the departure angle would be affected by a lower height? Would the general opinion be that the roof of the building and the ground (earth) are one and the same?

RESCUE RADIO: HAMS HELP IN AFTERMATH OF NYC JETLINER CRASH

Ham radio operators in New York City, still weary from the aftermath of the September 11th terrorist attacks were called out once again. This, after an American Airlines jetliner in route to the Dominican Republic broke up in flight shortly after takeoff from Kennedy Airport. The Airbus A-300 had 265 passangers and crew. It crashed moments after takeoff setting homes ablaze on thrr Rockaway penninsulia. There were no known survivors. We have more in this report:

--

When American Airlines Flight 587 crashed just minutes after takeoff from Kennedy Airport in New York City on November 12th, the Salvation Army was one of the first groups to arrive at the disaster scene. It brought in several mobile canteens to help feed rescue workers and residents whose houses had been damaged or destroyed.

The Salvation Army regularly uses ham radio operators in its SATERN network to maintain communications between its units at a disaster site. This being the second disaster to hit New York in two months' time, the Salvation Army Incident Commander asked the SATERN disaster command operator, Carlos Varon, K2LCV,to request additional ham volunteers. Operators were needed to staff the canteens and a mobile command post.

Initially up to a half dozen ham stations were to be set up at various locations near the crash site and another at Salvation Army Headquarters in Manhattan. It was anticipated that the communications mission would last three to four days.

Also, according to ARRL New York City and Long Island Section Manager George Tranos, N2GA, the League's Amateur Radio Emergency Service was on standby for the American Red Cross. Hams were later reported as providing communications support to the Red Cross for its operations.

But getting to any assignment was not easy. New York officials initially feared this was another terror attack and put the city into a near lock-down, closing all airports, bridges and tunnels for several hours after the crash. In addition, the crash site itself was on an island, and access to the area was severely restricted. All this made it difficult for ham volunteers to reach their assignments. Finally, they were all told to gather in one place where they would be escorted in by a Salvation Army command vehicle.

Among those who helped organize the ham radio response was Mark Phillips, KC2ENI, the ARR Emergency Coordinator for Queens County. The Rockaway Command station was Joseph Albertus KB2QLE and Net Control on the 147.090 MHz repeater was Michael Lunetta W2MPL.

From the offices of CQ Magazine, I'm Rich Moseson, W2VU.

--

Authorities who found the flight data recorder said it contains information leading to an initial conclusion that mechanical failure of the Airbus jet was the cause of the crash. (W2VU, WB2FXN, K2VMR, N2GA, and communications monitored on the 147.09 repeater)
**

RESTRUCTURING: RUSSIA SAYS NYET TO NO-CODE

The Russian Federation has said ‘nyet’ to no-code. According to the W.I.A. Victoria News, the Federation says that there are good reasons for the Amateur Service to continue with Morse as a license requirement for operation below 30MHz. It also says that it has no plans to make any changes to its domestic licence conditions. Amateur Radio Newsline’s Roy Neal. K6DUE, takes a look at the surprise Russian position:

--

"Keep the Morse Code." That's the position of The Russian Federation. It was revealed by the International Telecommunications Union on the 12th of October, when that organization released a position document for the World Radio Conference of 2003..

The Russian Federation told the ITU that it supports most changes to International Radio Regulation S-25, which sets forth qualifications for radio amateurs. But, says the Federation, keep the Morse code. Reasons? First a strong belief that Morse testing is the big difference between Amateur Radio and the Russian version of Citizen's Radio Services. The Russian Federation also points out that lowering the code requirement in many other nations has not led to a significant increase in the number of hams in those countries.

The Federation says that it surveyed Russian radio operators and found overwhelming support for retention of the code and the Russians say Morse is one of the most effective means of communication in emergencies with clear benefits in reducing interference on the high frequency bands.

What does it mean to the rest of the world, this decision to retain Morse testing? Jim Linton, VK3PC, is the author of Australia's "Morse Code Watch."

He says the Russian Federation's position can be accomodated easily. This because any new I-T-U Radio Regulation S-25 to come out of the World Radio Conference in 2003 will set only a minimum qualification standard for radio amateurs. It will not force that standard on any country.

For the Amateur Radio Newsline, Roy Neal, K6DUE

--

As previously reported, the IARU Administrative Council voted on October 8th to support dropping Morse as a qualifying criterion for high frequency access. It says that Morse testing is no longer relevant to the healthy future of amateur radio. (W.I.A. Victoria, W5YI Report)

**

THE 100TH ANNIVERSARY OF MARCONI'S HISTORIC TRANS-ATLANTIC RADIO TRANSMISSION

I’m Bill Pasternak, WA6ITF, in Los Angeles, with a late breaking bit of radio history.

December 12th will mark the 100th anniversary of the first Trans-Atlantic radio transmission by Guglielmo Marconi. To commemorate the event, The Marconi Radio Club and The Falmouth Amateur Radio Association radio operators are making plans to celebrate this important historical event from December 11th to the 16th. And in this very rare recorded interview supplied by Q-News, Marconi himself commented on the his first contact across the Atrlantic pond. Take a listen:

--
Audio of Marconi commentary here. No text available. Please listen to audio newscast. Links are at http://www.arnewsline.org.
--

The signal Marconi referred to was a series of the letter S transmitted using CW across the Atlantic from Poldhu, Cornwall England to St John's, Newfoundland. For this 100th anniversary, the Marconi Radio Club will be using the call sign W1AA slash CC and will be operating from Cape Cod, Massachusetts, U.S.A.. This was the location of Marconi's 1903 Trans-Atlantic radio station. Marconi's 1903 call sign back then was "C C"

For exact times, frequencies and modes of operation for W1AA slash CC go to www.qrz.com/database?callsign=w1aa) (K1VV, Marconi Radio Club W1AA. Marconi audio supplied by Q-News)

AMERICA AT WAR: G3 MAY HAVE TO WAIT

It now appears very unlikely that new G 3 personal communications technology will share the same spectrum worldwide. Amateur Radio Newsline’sa Henry Feinberg, K2SSQ, tells us the U-S military has other ideas:

--

While Europe and Asia have reached accord on commen frequencies for the introduction of G 3, the September 11th terrorist attacks in New York City and Washington have convinced the Departrment of Defense to take a different position. The DoD now says that it is not in the national interest to relinquist spectrum in the 1710 to 1850 Mhz band just because that happens to be the same spectrum to be used commercially overseas.

According to the latest issue of the W5YI Report the Cellular Telecommunications and Internet Association says that the Department of Defense will encounter interference from 3 G wireless devices but the DoD disagrees. It says that whatever equipment it has is far more powerful. The DoD adds that it may interfere with 3 G cellular telephones oversaeas but that the cellphones will not adversly impact on the military or its operations.

For the Amateur Radio Newsline, I’m Henry Feinberg, K2SSQ.

--

In other words, over here in the United States, if G 3 wants 1710 to 1850 Mhz -- its going to have to wait. (W5YI Report)

**

AMERICA AT WAR: EMERGENCY CELLULAR TELEPHONE PLAN

Verizon Wireless and the United States government are in the final stages of a deal that would give some emergency officials priority access to the company's cellular network. Under the agreement, about 2,000 federal, state and local officials would be given a code that allows them priority over others trying to make calls.

The system, intended to be used only in times of crisis, would be operational in New York, Washington and Salt Lake City, the site of the 2002 Winter Olympics. Verizon has submitted a request to the Federal Communications Commission, which must review and approve some elements of the plan. According to a government official who spoke on condition of anonymity, others trying to make calls could get busy signals because of the plan. (Published news reports)

**

ENFORCEMENT: FCC TO CB OPERATOR – TIME TO PAY THE FINE

The FCC has told a mid-West C-B operator that he has to pay the price of breaking the rules. This after the agency affirms a $9500 Monetary Forfeiture issued last summer to Klaus D. Kramer of Oklahoma City Oklahoma.

--
The Klaus Kramer story goes back to last February. This is when the FCC received several complaints of a CB radio station operating with excessive power in Oklahoma City. The Dallas office sent agents to locate the source of the transmissions. In the course of the two day investigation the agents traced transmissions to three locations including Mikes Cycle Shop. The latter is a business owned by Klaus Kramer.
The agents conducted inspections that revealed that Mr. Kramer violated Section 301 of the Communications Act by operating radio transmitters without authorization. Kramer admitted to making the transmissions and voluntarily relinquished the equipment. On March 12th the Dallas office issued two Notices of Violation to Kramer. In response to the Notice's of Violation, Kramer acknowledged the violations and indicated that he would discontinue operation of the station. On July 13th, the Commission's Dallas Texas field office issued the Notice of Apparent Liability for Forfeiture in the amount of $9500 to Kramer for the noted violations. Kramer filed a response to the NAL on August 14th claiming that the amount was excessive.
In denying Kramers appeal, the FCC's November 8th order says that its Dallas office has complaints regarding similar operations on two separate occasions in March 1998 and October 1999. In both of those instances, Kramer also voluntarily the offending equipment and on at least one occasion stated that the violations would not be repeated. None the less, the FCC says that its investigation has revealed that Mr. Kramer again: "...violated our rules" in February 2001. Thus says the government, imposition of the $9500 is not excessive and is proper in this case.
For the Amateur Radio Newsline, I'm Don Wilbanks, KC5MFA, reporting.
--
Kramer was given the usual thirty days to pay the fine. He also has the option of further appeals. (FCC)
**

ENFORCEMENT: FCC TO STATION OWNER - YOU ARE OFF THE AIR

Hams are not the only ones feeling the pinch of the Federal Communications Commission action. Five Midwestern radio stations have gone off the air after the agency denies an appeal by their owner who the FCC says was found unfit to continue to operate them.

Back in 1994 the owner was convicted of crimes involving minors. He was sentenced to an eight-year term and was released in 1999 after serving five. Last July he was told by the FCC that he no longer held the minimum requisite requirements to remain a Commission license. Also, that he would lose his licenses to operate the stations within 90 days.

Last month he petitioned the FCC to allow him to continue operating the stations. The FCC denied his request on October 3rd and the stations stopped broadcasting just after midnight October 4th. The FCC says it plans to auction off the station licenses. The owner is reportedly considering an appeal. (FCC, other published reports)

**

FCC NEWS: MASS MEDIA BUREAU APPOINTMENT

Nina Shafran has been named Deputy Chief of the FCC’s Mass Media Bureau Audio Division. Shafran joins the Commission from the staff of the Dow, Lohnes & Albertson communications group where she specialized in broadcast matters. (FCC)

HAMVENTION UPDATE 2002: DISPELLING RUMORS

If you are one of those who heard a rumor that the Dayton Hamvention is leraving its longtime home at the HARA Arena, then forget it. Its nothing more than the normally irresponsible Internet rumor mill working overtime. Bill Pasternak, WA6ITF, has more:

--
According to planners posting to the official Hamvention website, the erroneous rumor began the week of Hamvention 2001. This, after it was was allegedly printed in a Chicago newspaper that the HARA Arena had been sold. It had not been.

The Hamvention Committee spent the weekend of the 2001 event reassuring its vendors and attendees that HARA had not been sold. Also, that Hamvention's contract had not been "bought out" and that it would be back at HARA.

But that’s not all. The HARA Arena management issued its own formal statement. It also satated that the HARA had not been sold, and that it will not be razed. We at Amateur Radio Newsline were there. We heard it first hand.

Most important the HARA folks reitterated what the Dayton Amateur Radio Association has stated. The Hamvention will be there as promised. And as those of you who received last months mass mailing already know, the dates are May 17th, 18th and 19th, 2002. We will see you there.

For the Amateur Radio Newsline, I’m Bill Pasternak WA6ITF in Los Angeles.

--

So much for the rumors on the Newsgroups and other internet gossip spots. The real story is always at www.hamvention.org. (DARA)

EMERGING TECHNOLOGY: DTV ROLLOUT UPDATE

Roughly two-thirds of commercial television stations plan to broadcast a digital signal by a federal government deadline of May 1, 2002. This, according to the National Association of Broadcasters.

In a report to the Federal Communications Commission, the industry group said that many of those that won't make the deadline are waiting for equipment to be delivered and expect to have digital broadcasts on the air in the months afterward. But some stations in smaller markets are having a hard time paying for the upgrade, the association says.

Right now, most home television sets in use receive only analog signals. But congress has mandated that broadcasters must give up their analog channels to the government by 2006. As a result, there are concerns that consumers won't have made the costly upgrade to
televisions that can receive digital signals by that date. (News release)

**
HAM RADIO IN SPACE: ISS TALKS TO WISCONSIN SCHOOL

Students at Tremper High School in Kenosha, Wisconsin, asked questions the morning of November 6th of the International Space Station Expedition Three Commander Frank Culbertson that got some very personal responses. Culbertson told the teens that he certainly did not expect as much to be happening on Earth during his stay at the orbital outpost, in obvious reference to terrorist attacks. He said that he wished that he could have been with his family during the most stressful times, but he took comfort in knowing that they were strong, and could get by.

On a brighter note, Culbertson said that his current mission is the high point of his space career. He added that he hoped some of students at Tremper High can do the same thing some day.

In response to another question, Culbertson said that he hoped to see cheaper access to space, and hoped for a manned Mars mission and a permanent lunar base during his lifetime.

The contact was an event facilitated through the Amateur Radio on the International Space Station project, sponsored by AMSAT, ARRL and NASA. In all, fourteen students asked one question each during the contact. About 60 other students and a few teachers witnessed the event in person, while M-S-N-B-C carried the audio portion of the contact live over its website. (ARISS release by Gene Chapline, K5YFL)

**

HAM RADIO IN SPACE: NEW ANTENNAS HEADING TOWARD THE ISS

The International Space Station could have a new set of ham band antennas by early in 2002. The antennas are expected to be trtansported to te ISS this month and installed around the perimeter of the Service Module. This will give the I-S-S ham station high frequency, VHF, UHF and microwave capabilities.

The most interesting of all the new antennas is the high frequency array. Its made up of a two and one half meter long flexable tape that will definately work on 10 meters and holds posibilities on 15 and 20 as well. This particular antenna was a joint effort of the Italian, Russian and United States ARISS design team. (ARISS)

**

HAM RADIO IN SPACE: STARSHINE NEEDS TELEMETRY REPORTS

Ground controllers of the Starshine-3 ham radio satellite are seeking volunteer amateur radio operators and others worldwide to monitor and report telemetry from the recently-launched satellite. Starshine 3 transmits 9600 bit per second AX-25 protocol packet telemetry every 2 minutes on 145.825 MHz.

The satellite’s primary mission is to involve school children from around the world in space and radio sciences. Students should be able visually track the satellite during morning and evening passes by recording its telltale mirror flashes and reporting their observations to Project Starshine. To report Starshine 3 telemetry or to learn more about it, please visit http://epulation.com/starshine/starshine3. More information about Project Starshine is available at www.azinet.com/starshine. (STARSHINE vis AMSAT-NA)

**

CONTESTS: THE PSK-31 DEATH MATCH

Call it a truly different kind of contest. This, as the Michigan DX Association announces that it will sponsor the PSK-31 Death Match. The dates are December 7th through the 9th and a trophy will be awarded to the highest overall score. Just what is the PSK-31 Death Match and what are its rules? You can find out on the web at www.geocities.com/mdxa1/death match.html (Internet release)

**

DX

In DX, a big surprise for 6 meter enthuiasts. Jeramy boot, G4NJH, has the details:

--

A combination of high solar flux and low magnetic activity provided world-wide F-layer propagation on 50MHz during the week up to the 4th of November. Strong backscatter and the occasional Sporadic E openings meant that all continents were worked from the UK on 50MHz during the course of the week.

On Tuesday, the 6th of November, a solar coronal mass ejection hit the earth's magnetic field at 0150UTC and triggered widespread auroras. Observers as far south as central California reported seeing vivid displays of the Northern Lights, although we had no reports of visible auroras in the UK at the time of compiling this bulletin.

--

As we go to air 6 meters remains a worldwide D-X paradise. More information is on the web at www.rsgb.org and on the subscription VHF reflector. (G4NJH)

In other D-X news word that two Spanish operators will be in Cameroon between the 11th and 23rd of November. The pair will be working on the installation of HF and VHF stations in hospitals and missions. In their spare time they will be on the air as TJ2RSF on the High Frequenvcy bands. Activity will be mainly SSB, with some RTTY and CW. (VHF Reflector)

And Chris Post, N3SIG, who is a Firefighter and EMT in the United States Antarctic Program at the McMurdo Station on Ross Island is now active as KC4/N3SIG until March 2002. Post told the Ohio Penn D-X newsletter that he will be active every other day starting around 2000-2100 Eastern U.S. time primerally using SSB on 20, 18 and 15 meters. All QSL cards go to AI3D and be sure to include an S-A-S-E. (OPDX)

**

THAT FINAL ITEM: HAM RADIO IN LEBANON

And finally this week, a look at how ham radio is able to survive in Lebanon. Q-News Graham Kemp, VK4BB, looks at the nation, its licensing system and its Amateur Radio Community:

--
Wireless communication was first introduced in Lebanon by French soldiers during the French mandate; consequently, a number of curious and interested Lebanese took on this hobby and started operating under a permit and a call sign provided by the French Authorities.

With Lebanon gaining its independence in 1943, the Ministry of Post and Telecommunications become the issuer of the license to own and operate an Amateur station.

In 2000, there were 230 licensed ham operators in Lebanon, and anyone over 18 years is eligible to acquire a radio amateur license.

Maximum authorised transmitting power is 1,000 watts. The exam is prepared by RAL and is supervised by governmental officials. It comes in three separate parts, which involve multiple choice questions which include theoretical questions on electronics, antennas, and other technical information. Also rules and regulations of amateur radio, and the laws of communication. Also, a test on how to establish a vocal contact over the air.

Their Society is the RAL-- the Radio Amateurs of Lebanon which, like ours represent him or her before the Local authorities and the IARU

From Q-News Australia, I’m Graham Kemp, VK4BB, reporting for the Amateur Radio Newsline.

--

Truly an amazing story of how ham radio can survive even in the midst of geo-political problems that have plagued the Middle East for as long as man can remember. (Q-News)

Karl,
As the height above ground decreases, the 'departure' angle, or
'take off' angle increases. How much? Depends on the surrounding
objects and how 'good' the ground is. Same for the roof of a building.
If the roof is made up of lots of metal it'll be the same as a good
ground. Same holds true about the 'depearture' angle...

As far as effective departure angle is concerned: yes.

The terrain out to many wavelengths from the actual antenna is involved in composing the far-field pattern. So, you might think of the dipole mounted low on your roof as being about the same as a dipole mounted 30+ feet in the air on a pole, albeit a rather "fat" pole!

I am always suspicious of infinite SWR. The losses in 50 feet of coax will be small at 7 MHz, but will be enough to drop the SWR below infinity hi hi.

Seriously, you said that you checked for shorts. Have you checked for opens? If the line (or any connections) are open it can cause very high SWR.

You have to get to the wire of the actual dipole (even if it is up in the air) and ohm it out to the connector at the other end of the coax. Make sure you have low ohmage (<1 ohm ?) from the connector center conductor to one leg of the dipole and the same from the connector shield to the other leg of the dipole. Wiggle the connectors and the wires and see if anything changes.

If you have a balun in the coax line, you will not have an ohmic connection and have to try some other troubleshooting method.

Good luck. This sort of problem can be very frustrating, especially if you have to take the antennea up and down a few times. Just keep at it.

> WB0VZZ
==========
It's a good idea to think about height above ground in terms of wavelengths. So a 10 meter dipole at a height of 10 feet above ground will perform much the same as a 160 meter dipole at a height of 160 feet.

The foregoing assumes both antennas are in the middle of a broad, well-watered, agricultural plain with no obstructions. In practice, erecting an antenna atop the roof of a building has several effects -

(1) If the roof is broad compared with a wavelength then the height above roof is much the same as height above a poor ground and there is no improvement on that account.

(2) But being located above a roof will give a clear take-off above the obstructions caused by other buildings of the same height. If there are many such obstructions there will be a considerable improvement on that account.

(3) At lower frequencies where building height and breadth are of the same order or smaller than a wavelength, erecting an antenna on a roof has the effect of increasing BOTH the effective height above actual ground AND height above obstructions. And so a much better performance can be expected with confidence.

As for radiation patterns at HF, predicted patterns occur only when antennas are located in flat plains with not a building in sight. Not even a radio shack. When near the ground in the midst of buildings radiation patterns tend to become random. Putting an

antenna on a roof just changes to yet another random pattern.
Depending on how electrical conductors and girders are placed
within the building structure, relative to the antenna, practically
anything can happen. Best not to worry about it. Suck it and see
!

I'll disagree with most of the others... If the antenna has a poor RF ground, and he is running the power you claim, RF could conceivably enter through the mike cable and adversely affect the audio stages..

Message-ID: <i8VJ7.13525$%p4.1700351@news6-win.server.ntlworld.com>
Source record: 154606

I have been using an open wire fed sixty foot doublet and SGC 231 auto ATU for several years now and am wondering if there might be a more effective antenna that I can use. I use all bands from 40-10M, but not really seriously, I just have a listen round the bands and try to work any interesting stations.

I have a 40' steel and fibreglass mast at the end of the garden and the house at the other to act as supports with the ATU in the middle. The current antenna seems quite noisey so I have been thinking about a loop etc, I could fit in a 40m full wave loop but would this work well on the other bands. I have also been thinking about replacing it all with a Gap Titan DX as this might suit my needs better as an occasional ham.

Any suggestions greatfully RXed.

Jon G2FHF (ex M0BQQ)
PS - My garden is 60' long and 15' wide so a mini beam will not fit.

Mark---before you are assualted by folks....do a Deja search for this topic...lots of previous discussions. There are two schools of thought:

---"It's a dummy load supsended in mid-air and an unacceptable radiator."

---It is a useful antenna for those who need the ability to use the frequency range between 160 and 10 meters without a tuner and who may have to move frequency quickly (ALE for example). It is NOT as efficient as a dipole antenna cut for any given resonant frequency; it is expensive compared to what you can homebrew.....BUT, if you understand the pros and cons and are willing to accept the degraded performance to gain the flexibility you might need it is a viable solution. The military and many goveremental agencies have been using these all over the world for many years with good results.

If you decide to use one I'd spend the extra $$ and go with the stainless steel version to maximize useful life...it's what I use for both ham and MARS operations.

Unfortunately, it doesn't have to be a commercial airport. If it is on a FAA chart as a place to land, it counts. Get your GPS and see how far you are from the nearest point on a runway. That is the criteria. Then get a copy of the (FCC amateur Part 97 , and FAA navigable airspace [AC 70/7460-2K]), rules which spell out the height vs. distance. The FAA document has nice drawings.

2161. RF in the car-shack

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-18 22:59:45 UTC
From: John Wagner <john@wagner-usa.net>
Message-ID: <3BF83E28.8565D19E@wagner-usa.net>
Source record: 154613

Hello,

I previously ran HF Mobile on 20m with an FT-817 at 5w to a hustler mag mount vertical on 20m - worked like a champ however I realized that I wasn't taking the FT-817 out much and I sometimes needed more power. I recently acquired a QRO rig, an IC-706MKIIG and decided to blast out at a 100w. Ouch. My homemade paddle (copper PC Board) got real hot and I noticed the display on the 706 flipping around a bit. When I turn the power down to 5w, everything is OK. I made a coil out of the coax feedline (6 turns is all I could muster before running out) and things are better, however I still can't run the full 100w without problems. About 20w is all I can do before the RF in the car-shack starts being an issue.

The car is a Mazda Protege DX (and it has worked some, even at 5w ;)). Mag mount antenna is on rear hood and I have not made any other mods to the car like running grounding braid or bonding panels together.

Any thoughts on getting rid of the RF in the car so I can (when needed) run QRO?

Thanks es 73,

John, N1QO

well I won't get into the argument with the others but as a former truck driver myself with those new fiberglass rigs, Get a 102' Stainless steel whip mounted to the catwalk. You have a true 1/4 wave and a great ground working for you

If he reall wants to sound off dual 102" monted by the catwalk hanging off near the windfairings will do wonders.

Cross-posted to: alt.ham-radio.marketplace,rec.radio.amateur.antenna,rec.radio.swap

For sale...

Tri-Ex TM-358 Sky Needle tower. Includes 58' three section tubular tower, newly recabled with SS cable, 10' thickwall mast, complete motor assembly for controlled extension and retraction, CDR sized rotator cage assembly, new hinged base, instruction manuals, a 1997 UBC stress analysis, blueprints, and even the side mounted ladder!!!...the whole enchilada.

Tower is down and next to my home. It is HEAVY (on the order of 1500#), so it will take a wrecker to lift it out of the yard and onto your car trailer. To install you will need to manufacture the re-bar assembly that goes into the hole, gather up the gears and thrust bearings for the rotator assembly, and lots of labor!!

This is the cadillac of towers. Very strong, unlike the flimsy tubular towers that are so much cheaper. Rated at 12.4 square feet at 60mph, 7.2 square feet at 78mph, and 3.6 square feet at 95mph while fully extended!! Dead weight is 400# including rotor and rotor cage.

$2695.00

Located in Thousand Oaks, CA (45 miles NW of LAX).

Source record: 154617

Mark,
Yes, I've had experience with the B&W folded dipole. In a nut-shell, don't bother, you will be disapointed. It 'works', but not very well on any band. The higher the frequency the 'better' it works, but that really isn't much of a recomendation since almost any doublet will do the same thing.
Others have recomended that you read the reviews of this antenna, and I agree, don't just take one persons experience as to what the antenna will/won't do.
Paul / W5LZ

2166. Re: Antenna recommendations please

Newsgroup: rec.radio.amateur.antenna

Source record: 154618

Jon,
Why not give the loop a try? It's a fairly inexpensive
antenna to make, and you already have the feedline and tuner to
make it usable on 40 meters and up. If your not happy with it,
you can always put the doublet back up.
I'm not much of a vertical antenna fan, so the 'GAP' or any
other vertical would be my next to last choice for an antenna.
No matter what the advertisements say a good ground system can do
nothing but improve a verticals performance (not just a vertical
but any antenna).
If the loop doesn't work out for you, you can always try the
'GAP' and not be out much for the loop.
Paul/W5LZ

PS - Last place on my 'antenna list' is reserved for future
antenna projects that don't work...

Kev:
Anyplace that an airplane can land and takeoff from is a real airport.
What you really meant was that is is not a commercial airport. You are
still limited to a maximum tower height along a line from the end of the
nearest runway to a point 200 feet above the altitude of the runway at a
distance of 2 miles. Also if you build a tower over 199 ft 11.999999
inches above the ground to the top of the antenna you must provide red
lights from dusk to dawn.
Years ago I installed a tower for our local repeater. We went 160 feet
and added a 22 foot antenna mast. This kept us below the 200 foot mark
and did not limit our range over what the extra 20 feet would have given
us.

John,
Mag-mounts have limits, you may have exceeded your
mount's limits. Thats the first thing that comes to mind.
To make the key and '706 act as you say, there must be a
~lot~ of RF floating around! I think that would indicate
more than just an antenna ground problem. Since the '706
will require much more current than the '817, is your power
line to the battery large enough to handle the current draw?
That's sort of a 'reach', but you never know. Good luck.

The "allowability" of a 50-100 footer most likely will be within the
jurisdiction of yer local building code or other neighborhood
regulations assuning no CC&Rs are in place. But before you go thru any
pushups with the local bureaucrats it might be a good idea to first
get a "building permit" from the XYL or yer equivalent thereof. I've
known a few of those who have strong opinions about maximum allowable
tower heights, etc . . .

Hello Mark,
You might be interested in the W9INN MPD-5C dipole antenna. It comes in two different models ..either 78 ft long or 87ft long with slight performance (bandwidth) differences between the two. This dipole offers true 5 band performance with resonance on 10-15-20-40-80M. It is also rated at 1500W PEP

More details ,illustrations and real-world measured data is on the W9INN Page of the website listed below.

Hello,

I'm a newcomer to amateur radio. I have a technician class license and I would like to get involved with packet radio. I live in an apartment in New York City and don't have access to the roof to mount an antenna.

I was wondering if someone could recommend an antenna that I could purchase or build, which I could mount or prop near my window which would allow me to take part in packet radio communications.

Thanks in advance,

Ben Gross

If you want to work on 2M or 440Mhz I would recommend a J-pole antenna. You can easily build one yourself for just a few $. The easiest is probably one made from twin-lead, which makes it easily portable. I have also had good results with a J-pole made of copper tubing.

See the following for some ideas:
http://www.qsl.net/wb3gck/jpole.htm
http://people.ne.mediaone.net/buck0/hampage.htm
http://www.ac6v.com/antprojects.htm

Have fun!

There are several phenomena at work when working JAs on 80 from just
about anywhere in the U.S. except maybe from our northern West Coast.
First comes the realities of an S3 signal report on 20 becoming
magically transformed by some "mysterious mechanism" to an S8 on 80 on
the long haul stuff. Has nothing to do with the actual level of
nanovolts at the rcvr antenna connector. Has everything to do with
vivid imaginations and feelgoods. Nobody dies, what the hell, 589s
look good on QSL cards . .
>
>
Beverages have "gains" on the order of *MINUS* 30 dBd so that puts
them to bed as far as JA ham signals actually twitching any stateside
Beverage user's S-meter to the S8 level. But Beverages simply do not
inhale noise and they are very directional which are their big tricks
and is why the Big Guns can be expected to solid copy the JAs when you
can't. So the Big Guns incidentlly pass out "creative" 589s to JAs,
bleh, no biggie where they come from.
>
>
Your quarter wave 80m vertical is a noise magnet, believe it, the
noise it sucks in is burying the JAs yer S-meter "S1 noise reading"
aside. And for cripes sake turn the AGC *off* and disable yer stupid
s-meter before it drive you any nuttier. If ya can't actually hear the
guy's signal ya can work him via changes in the noise level on his
freq. Low-band dxing is not a science, it's a art form centered around
yer EARS. Or put up a dipole and get the noise level down.
>
>
There are of course propagation flukes. Back when I was going ape
trying for an early 5BDXCC I fired up on 80 instead off trucking off
to Le Job one morning and tuned the bottom end 80 with the 'ole 75A4
and holycow that's a 569 JA calling CQ! I only had a 135 foot inverted
L. No, he can't be a real JA! Yeah, well, I called the guy, bagged

him, signed, and found myself the object of pileup of JAs calling me when I shipped a rawther pompous "QRZ JA de W3YIK?" from here in Philly. I worked around fifteen of 'em over maybe ten minutes before the band completely collapsed. A couple of 'em sent ME sase's! Life is all in the timing, eh?

I can second the success of a jpole antenna. I live in a restricted community, in that I can't put up an antenna on the house we own. I purchased a Jpole antenna from Arrow Antenna in Cheyenne, Wyoming for $39, and can vouch that it's a solid performer. I can hit repeaters within a 20 mile radius or so full quieting on 10 watts. On 50 watts, I can hit repeaters within about 35 miles full quieting, and can hear them reasonably well. This is with the antenna in the closet, on the 2nd floor.

>
> Comments?

The B&W antennas work, and have been widely used around the world by government agencies. I once was in a position where I met a daily state National Guard HF SSB net on 8 mhz where a couple dozen stations scattered around the state at up to 300 miles distance all had 100 watt transmitters and all used the B&W antennas. At no time did any station ever fail to communicate very sucessfully.
I'm sure they would never have been bought by Uncle Sam in the quantities they were for use in embassies etc if experience had shown them to be unusable or even marginally so.
That said, they are indeed poor performers when compared to more efficient antenna types, and I can't imagine that you will gain anyhing by giving up the G5RV in favor of one. In fact you stand to lose.

Source record: 154535

Richard,
Let me add a bit to my other post and maybe clarify what
I intended to say.
While there are many amateurs who are competent enough to
design and install maritime radio systems, there are many more
who are not (my self included despite the commercial license I
also hold). A 'serious' radio system, one you would trust your
life to, has many characteristics that the average amateur radio
station does not have. The 'nuts and bolts' of a maritime
radio station are certainly not what is usually required or
found in amateur stations. For example, how many ground straps
made from copper braid have you seen in an amateur station, and how
long would those same ground straps last in a maritime station?
Thats why I said it would be advisable to talk to the people
who normally do these kind of things, they are familiar with the
'practical' aspects of installations.
I agree, the 'Handbook' is certainly handy to have around, but
it doesn't cover some of the things that need to be covered for
'serious' maritime operations (and I wouldn't expect it to).
'Doc / Paul / W5LZ

I own one of these and they are NOT stellar performers. But they do allow you to load up on any frequency and put out a decent signal. The real benefit is in its receive capability. It's inherently quiet and broadbanded. Imagine having to cut dipoles for every band in the spectrum...I use it with a multicoupler, which allows me to listen to five receivers on five different bands, without having to worry about antennas resonance for each of them. Hence, the antenna does fine for me...

I believe the G5RV will give better results and you should stick with it, but if your goal is to run an antenna without the need for a tuner the B&W is not as terrible as some claim. I used one many years ago and had great success with it on 40 & 80m. It was strung horizontally from 10ft to 35ft at the ends and was a great NVIS antenna. The last time I used a G5RV was on a camping trip with my FT-817. The antenna was horizontal at 25ft and it worked fantastic on 80, 40 and 20M operating at 1/2 watt. If you are running 100w with the B&W and it is several dB worse than complete overkill, who cares? If you get it at a suitable height it will radiate and you will have fun. If your main audience is within a few hundred miles of you on the lower bands the B&W horizontal at 20 to 30ft will kick ### on any of the expensive verticals by GAP, Cushcraft, etc. If you get the B&W at proper height I would not be surprised if it outperformed most of the so called DX vertical antennas just mentioned. Someone will probably be offended because I don't have the same opinion but that's my experience with these antennas. Sorry if yours is different, that's what the hobby is about.
73,
Mike.

I used to run packet on 2 meters from an apartment, and it doesn't take much, antenna-wise. I used a Larson 2mtr/440 combo mobile whip, on a magnetic mount, attached to a silver serving platter (my "ground plane"). You could also put the mag mount on a metal filing cabinet, or the top of the refrigerator -- whatever. With this, I was able to hit just about any repeater in Houston for FM voice or packet.

The 2-meter j-pole others have recommended would work well, too. You can build one from tv twin lead -- see http://www.n1uec.org/n1uec/2meterjpole.html

Have fun!

Benjamin- My first 2M antenna was a ground plane made of copper romex sections about 20 inches long, soldered onto an SO239 UHF fitting, and suspended from the light fixture in my room. I worked packet and voice with an HT (FT-411 and FT530) with repeaters over 35 miles away. I replaced the GP with a dual band (144 MHz and 440 MHz)antenna with a mag mount on the top of a 5 drawer file cabinet. I actually used it in preference to a Cushcraft dual bander, mounted on the roof, because I picked up too many stations with it.
Of course, your building may have more metal in its structure than Mine, so it may be better shiedled. However, the point is that simple antennas frequently work well, so just put something up, and keep records enough so you can see differences as you make changes. (and, probably, you will).

Sounds like the lack of a good antenna ground connection is the main
problem. Also the mag mount doesn't help much. The coax isn't as well
decoupled as a mount through drilled the metal either. Unfortunately,
you need the best grounding at the antenna base itself. Also bonding
the car together helps, but won't do much if the antenna base itself
is not grounded well. MK

I think you about as well off keeping what you have. Noise just means
the antenna is working. You could try the loop, but I don't know if it
would be any better. I think what you have would outdo the gap on most
if not all bands. "Assuming your tuner is fairly efficient". MK

There is a simple answer as how high Antenna towers should be :

As high as your Money will reach !

2195. EZWires and EZPlots for use with EZNEC

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-19 06:57:42 UTC
From: "Dan AC6LA"
Message-ID: <G32K7.29878$xS6.47709@www.newsranger.com>
Source record: 154547

EZWires and EZPlots are two Excel spreadsheet programs that are designed to extend the capabilities of the EZNEC Version 3 antenna modeling package.

EZWires helps on the "input side" by letting you do "Modeling-by-Equation" with EZNEC. You can define the wires of your antenna model using a pair of enhanced spreadsheets and then pass the wire set over to EZNEC to complete the simulation. The program comes with several samples, including quads, a delta loop, an octagon helix, and templates that may be used to quickly build 40 of the ARRL Optimized Yagis.

EZPlots helps on the "output side" of EZNEC by offering a convenient way to plot many of the data items that can be produced with an EZNEC frequency sweep. EZNEC itself can plot SWR versus frequency and can show far field trace overlays for different frequencies. With EZPlots you can see additional items such as source R and X versus frequency or Forward Gain and Front/Back Ratio versus frequency. You can "take a snapshot" of any plotted line to allow easy A/B comparisons between modified versions of the same model or even between two completely different antennas.

Doc, W5LZ wrote:
"While there are many amateurs who are competent enough to design and install maritime radio stations,---."

Doc`s point is well taken. If you need to bet your life on something, you want the best odds you can get.

With an excellent ground just over the side, it`s still possible to have ground problems. Many pleasure boats have fiberglass hulls which should not present a big problem, but sometimes may.

In power boats, there are often noise problems. These may require shielding and grounding. It must be right, to suppress the noise, and as Doc mentioned, ground straps can be a problem. Your fiberglass boat may be like a Corvette, (the car) except that GM already took a number of measures in the car to tame the noise, and the car is unlikely to reside in such a severe climate for so long.

The radio installation must be designed for its environment and maintained for the demands placed on it.

The original question wasn`t about the perils of doing the job yourself. It was: "Can you refer me to HF antenna designs for sail yachts?". The "ARRL Antenna Book" has: "HF Antennas for Sail Boats" on page 16-32, and "Antennas for Power Boats" on page 16-39. Doc is correct again. The information is incomplete.

Best regards, Richard Harrison, KB5WZI

Ben,
Since packet communications generally takes place between
fixed stations (I said GENERALLY), why not build a 4 or 5 element Yagi
that you can mount permantly mounted (or easily turned by hand) to
your target packet station(s)? For 2-meters the boom length should be
reasonable. As a matter of fact, I've read in QST about a 1/2 height
Yagi that was used in an attic mount situation with good results.
Can't remember the issue, but a search on the ARRL website should
produce results.

Just went through some of my back issues. The July 1999 issue
of QST had an article on making a 5 element 2-meter Yagi out of a
Radio Shack TV antenna. Might be worth looking at...

From: marvin rosen <raghead@worldnet.att.net>
Message-ID: <DF8K7.175880$3d2.7557348@bgtnsc06-news.ops.worldnet.att.net>
Source record: 154553

what is the feasability of using 2 antenna tuners for one random length wire antenna? one tuner in the shack to "tune" the coax, the other tuner (LC NETWORK) resonant on 80 mtrs. which is connected to the antenna on the roof... would i be able to work 80-10 mtrs with this set up?

2202. T antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-19 14:49:18 UTC
From: Ian Liston-Smith <ian@wireless-sparks.freeserve.co.uk>
Message-ID: <7e6ivtso3hs7p3qatg66abftpcdrjpd4b8@4ax.com>
Source record: 154554

I'm trying to design a T antenna for the low freq end of 160m. I have a max 40 meters across the top and a max 10 meters drop to earth. I've searched ARRL/RSGB books etc. but cannot find the optimum top 'legs' to drop length ratio.

Is using the max 40 meters across the top OK and tuning it at the base the way to go? All the diagrams show a max top length no longer than the drop, but don't know if this is important.

I feel that the greatest top length possible will increase the virtual height, but can one go too far before the tuning becomes too difficult?

Thanks for any help.

Ian, G4JQT

Reg wrote:
"When that appears in a specification, what follows has only

Reg quoted advertising puffery I had repeated.

BoatAntenna.com aims to entertain. That`s how they sell. They pick words to favorably impact a prospect. "High performance" with respect to what? "Length" may imply that 16 feet is optimum for a 3 MHz antenna. I`d take more if I could get it. "High gloss" and "powerful brass" are pure entertainment.

Baloney aside, an item advertised for a particular use had better be usable. In a litigious society the purveyor may else be held liable. Notable but unsaid is that vertical antennas are offered while horizontal antennas are not. More than ease of installation is involved in this choice. The image in the sea of a horizontal antenna is reversed. A demonstration of this reversed reflection may be seen in the righting in your rear-view mirror of the word AMBULANCE painted in reverse on the vehicle.

The phenom of the reversed reflection of a low horizontal antenna that causes cancellation of signals directed at the horizon can be seen in the 1955 Terman`s on page 883. The effect is severe when sea water is the reflector because the sea has such high conductivity that the reflection is about as strong as the incident signal. Anywhere out on the horizon, the phase between incident and reflected waves is nearly 180 degrees from a low horizontal antenna. For a strong signal along the surface of the sea and at low elevation angles without the use of very high antennas, vertical polarization must be used.

Best regards, Richard Harrison, KB5WZI

The fixed network values needed at the antenna on 80m would probably
cause a severe mismatch and losses on 10m. One solution is to install
an autotuner at the antenna configured as an inverted-L with a
counterpoise. My solution is on my web page.

Jon:

For a technical, real online test of the GAP Titan DX you may want to visit the link below.

http://www.qsl.net/aa3rl/titandtl.html

Mike Banz did an excellent job with his comparison tests of the GAP to monoband verticals, and has all the data presented from EZNEC and from his actual contacts. His information helped me decide that since I had no space and no room for ground radials that this was the compromise to accept. I am very happy with the performance of the GAP and have worked some DX on each band with the exception of 80m.

Good luck,
73 Dennis - W6NYC

Also visit: http://www.eham.net/reviews/detail/315 for many reviews of the GAP Titan DX

Aren't newsgroups wonderful! You need information about antennae and you have instant access to a bunch of folks who really know! I've perused some of the postings, and a) haven't seen one specific to my question, and b) note that most of you are much more technical on this subject than I will be able to understand unless you tone it down for me. Keep it very simple, please!

It also looks like a lot of your discussion is on CB and such, while my question is about FM radio.

I have a friend who lives in a little mountain town with about 100 miles and a mountain range between himself and any radio station. His elevation is probably a bit higher than any broadcasting source, but still there are higher mountains between. He'd just like to get a nice clear reception on the public radio station from Laramie, Wyoming (nearest favored station) in his workshop. Any suggestions? (No building codes/covenants, but constant high winds are an issue.)

In my reading on other 'net sources, I see that an antenna similar to a TV antenna might be used, but it was stated that this antenna is designed specifically for FM radio. It happens I have an unused antenna sitting in my attic--the former owners left it. How could I tell whether it was for FM or TV? (If it's for FM, I'll give it to my friend, but I'd rather not haul it out of the attic for nothing.)

Thanks!

Is it just me or every time you walk into my local Radio Shack are you bombarded by the "need a cellphone?" and "we have great deal on satellite dishes" comments from the employees and managers. Yet these same idiots don't know shit about electronics. I mean shit its called RADIO shack not CELLULERShack or DIRECTVSHACK.

Saturday I walk into RS looking for 20 - 25' of electrical cord and employee says don't sell electrical cable by the foot anymore? I say OK how about an extension cord I can cut up? Guy shows me cords and all extension cords are 15' or less and expensive as hell. Then he jumps right into the need a phone need a satellite dish routine. They are so damn annoying. Not to mention I have been in there a bunch of times and told them I have a dish and am wearing a cellphone on my belt! While looking for some BNC connectors all they kept bragging to each other about to how many dishes they had sold or hoped to sell today. What a bunch LOSERS. Place was full of cheap Chinese electronic toys that they sell for twice what Toy s R us or Target gets for them. And dated computers and electronics all selling for a premium. Who buys a DVD player or a TV at RadioShack???

These guys have to be dying a slow miserable death how can they stay in business? My local store has 1 clueless MORON manager, 1 clueless assistant moron manager and at least 3-4 Moron trainees. Usually there are 3-4 working anytime I go in there how do they do it. How much can they really make selling cellphones and dishes?

2208. Kenwood TH-F6a Antennas

Ian Liston-Smith wrote:
"I`m trying to design a T antenna for the low frequency end of 160m. I have a max of 40 meters across the top and a max of 10 meters drop to the earth."

The best you can do is use everything you have. The horizontal top provides capacitance to reduce the inductance needed to resonate what would be a 1/4-wave grounded vertical antenna. The "10 meter drop to earth" is too short to be a really good radiator at 160m.

ON4UN`s "Low-Band DXing" on page 9-24 says:"To bring a short vertical to 1/4-wave resonance, the total T-wire length (top wire) should be about twice the length of the missing portion of the vertical mast."

Ian`s required 40 meters of vertical length for 160 meter resonance is missing 30 meters. By ON4UN`s formula, the horizontal portion of Ian`s T needs to be 60 meters long with the vertical wire attached at its middle.

Ian`s 10 meters of vertical and 40 meters of horizontal capability might be better used as an inverted L which could be resonated with a variable capacitor. The capacitor has lower loss than a loading coil.

The horizontally polarized radiation from a wire so low (10m) at 160 meters might mostly warm the clouds, but the current loop is in the vertical part and might do well at lower elevation angles, configured as part of either a T or L.

Best regards, Richard Harrison, KB5WZI

If I'm not mistaken, the R7 has some places where there are insulators between runs of tubing. It might be pretty difficult to stiffen things properly (avoiding the weak points Ian mentions), but I agree with Ian's comments about a relatively loose fitting wood rod. You can get long dowels with round cross-section, too, though more commonly only in large diameters.

Another option for guying, if you have no place to tie off the guys out from the base of the antenna, is to put spars out from the antenna somewhere around half way up the mast (antenna tubing), and run lines from (near) the top, over the end of the spar (and anchored to it), converging back at the bottom. You'd need to make both the lines and the spars from something non-conductive. It's common to use four such lines. You could probably do the spars with PVC pipe and fittings. For very long masts, you can have spars at, say, 40% and 75% of the way up the mast. Best to not have the mast divided into equal length sections, to avoid mechanical resonances. Beware that this strengthens the upper part but puts a lot of bending stress at the bottom: be sure things are strong in the vicinity of and below the bottom return point for the guys.

Cheers,
Tom

Well, that can be tough. In places where absolutely no signal penetrates, there is no chance an antenna of any size will help. It sounds from your wording, however, that he gets signal and wants to improve it for a particular frequency.

That's important. First that signal is there, and two that it's a particular frequency.

As general rule for this problem, make a wire antenna...very long.

What a multiple element antenna like a tv antenna, it solves two problems...it gives gain in a particular direction, and is tuned for a certain set of frequencies, and it reduces reception of signals on the frequency from OTHER directions. But in a hole in the mountains, I think directivity isn't that valuable. A very long resonant wire has the virtue of gain, and isn't really directional unless you make it very high. Therefore if his best reception is in the direction of some mountainous reflection as opposed to the actual direction of the transmitting station, you have still helped it.

If he wants to tune other stations too, fatness of the antenna conductor might be important. In general, the fatter the conductor, the more broadbanded, meaning more "channels" you can reasonably receive.

Let's say he wants to hang a good antenna to receive 96.3MHz. 300e6 m/s is the spped of light (and radio waves). So 300/96.3 = 3.12 meters. So about a 9.5 foot wire is a full wave. Make it a "long wire" by multiples...19 feet? 28.5 feet? Do some minimal trimming to tune in to the target frequency, but not much.

Connecting it to your radio? Use some Alligator clips, like you can get those jumpers at radio shack.

A note on orientation: FM transmitters' antennas tend to be vertically polarized. So make your antenna vertical for even better effect.

sounds like a grounding issue to me i would pound in a good 8 foot
ground rod you can get these at radio shack or home depot and then run a
good heavy copper wire into the shack and hook to the radio and tuner
and anything else in the shack and that should cure it
also check your coax connections

I want a small sized 35' - 45' crankup tower.
Probably going to put a Hexbeam or some other
small sized beam on it with a Yaesu rotor.

What is a good high quality choice of tower?

Or what is a tower to stay away from?

Do they usually come with all the hardware to bolt to concrete.

How big of hole??

I just got a small mobile CB to put in my car.
Since there is the possibility that I will also get a VHF/UHF
mobile in the future, I was thinking of buying a good antenna
that can be used with both. Is this possible? I am thinking that
it won't be easy since there is a big difference between the
27MHz of the CB and the 170MHz of the VHF amateur band. On the
other hand I am new to all these and I may be missing something...

thanks,
Andreas

Do you work for RadioShack? Sounds like offended a RS employee. First off, I really don't appreciate your asshole comment especially since you don't know enough about me to form an honest opinion. Second, I don't have to justify walking into Radio Shack do I. Like I said they advertise that they sell Radio and electronics does not electrical cable fall into that category? Finally, I went there because they are close to my house and I don't want to stand in line a home depot for a half hour for electrical cable. Not that I owe you an explanation, loser.

Hi capra,

They are called ordinary wall sockets. GFI works on the principle of common mode current flow that trips the internal breaker. You have a common mode problem - try some form of feedline isolation like a 1:1 balun or other choke at the antenna.

I have been in sales all my life own my own business and have trained many salespeople. I will give you free a tip friend, a GOOD salesman values each and every customers business and treats all customers with respect no matter how small or large because you just never know. That few feet of cable or resistors today can turn into a $1000.00 sale next time or a $10,000.00 in repeat business over time but not if you blow it on first contact. My best contacts have been made when I least expect it.

Also, calling the people at RadioShack (or insert favorite retail electronics superstore) a SALESMAN is an INSULT to anyone who actually know how to sell ! And those DirectTV dishes they were bragging about were being sold at $.01. Go check it out, they will sell you a DirectTV w/ activation for $.01, wow that really tales some sales skill. How much of a kickback can DirectTV possibly be offering? Sprint / Verizon phones start at $19.95 w/ activation. Come on they would be lucky to be able to eat a value meal a McDonalds let alone steak.

And the funniest thing is that of the employees I have talked to most have no idea how DirectTV works, what all the plans are, what the small print in the agreement says or anything else. Same goes for cellphones, I actually saw a guy tying to sell a Sprint phone compleately misrepresent ALL of the SPRINT PCS policies and technical capabilities of a particular PCS phone (I am longtime Sprint PCS user).

I really like the telescoping tubular towers ,especially for the small antennas (I recommend the 2 element 5 band lightning bolt quad).The hole will be about 3x3x6' deep.Most come with bolts but you have to wire together the rebar cage.Usually the worst part of buying a tower is getting it shipped.TG

You don't need two tuners if you feed with ladder line. The ladder line has such low losses the mismatch doesn't matter.

I run a 102 foot long center fed inverted L fed at the top. Think half a dipole on one side and an up-side-down vertical on the other.

It is fed with 130 feet of ladder line out of a tuner here in the shack. Works pretty fine on 80-10.

==========
Ian,

With T antennas there is no such thing as an optimum
"length-of-top" to "drop-length" ratio.

"Drop-length" is the most important factor. The longer the drop
(not necessarily the antenna height above ground) the better the
performance will be up to the point when the vertical part of the T
is about 1/4-wavelength. Above that height the "top" is no longer
needed. The top is just sort of capacitance top-hat.

At low heights compared with a 1/4-wavelength the longer the top
the better - up to the point when the height plus half the length
of the top is about 1/4-wavelength.

The above assumes the vertical part is tapped into the middle of
the top. But it matters very little whether it's tapped into the
middle of the top or anywhere else along it. If tapped into the
end we have the common or garden inverted-L. Performance-wise
there's little to choose betwwen them. The centre-connected T in
your back yard may have hardly-detectable lower radiation angles.

Another thing to take into account is that the "length-of-drop" is
not the height above ground of the "top" but is the overall
length of the "drop" from the top to the transmitter which is

usually appreciably longer. Unless, of course, your shack is the garden shed directly under the antenna.

Tuning never becomes difficult for such arrangements.

In your situation, ability to erect a wire, 40 metres in length, at a height of 10 metres is just fine. It doesn't matter whether you connect the vertical wire at one end or the middle. Radiating efficiency will be good. The only difference you will notice will be the tuner L and C settings.

Since you will be tuning the antenna against ground a moderately good ground connection is advisable. But this need not be more than your domestic plumbing system plus 3 or 4 shallow-buried radial wires 15 to 20 feet in length in random directions. Plug your ears against the ridiculous magic number of 120 radial ground wires each exactly 1/4-wavelength.

Download programs ENDFEED and TANT136 from website below to get the feel of things. TANT136 is primarily intended for the 136 KHz band when using an HF centre-fed dipole as a T antenna with the feedwires strapped and fed against ground but can be shifted up to the 160 metre band. Program ENDFEED covers inverted-L's and verticals. Both programs put you into the right ball-park regarding antenna tuning component values when using various ground electrodes.

May I suggest you erect an 80m band dipole, also very efficient on most other higher frequency bands when fed with 450 or 600-ohm line, and it will go like a bomb on 160m with the feedline wires strapped and tuned against ground. You lucky fellow !

Download progs in a few seconds. No unzipping inconvenience. Run immediately.

Richard offers one approach, but it sounds like an additional problem lies in your statement that the R5 is mounted only a few feet away from the rig. You and the radio are in the relatively strong near field of the antenna, and it will be very difficult to minimize that effect short of building a screen room around you and the radio.

It won't hurt to try various grounding and isolation schemes, but if it were me, I would look seriously at moving the antenna as far away as possible.

My Butternut HF9V is about 30 ft away from the wall of the shack and I experience no ill effects at that distance.

But if you are runing much power - you didn't say or tell us what radio - you are in a region of volts/meter of r-f field strength, and it is not surprising that you are having "r-f in the shack" and GFI problems.

I learned everything I need to know about you when you got to the end of
your rant and started calling everyone at your local Radio Shack a
"Moron".

Your feelings are 100% correct, more like 92 actually. Mobile antennas have to be resonant at an odd quarter wave in most cases so the 5th harmonic of 27 being pretty close to the two-meter band (144-148) at first gives you hope that a plain 9ft whip would work. The problem is that antennas beyond 3/4 wave tend to end fire which would give you a great radiation pattern straight up on VHF.

If you went to a base loaded antenna, the VHF would simply disappear in the rf choke the loading coil would present. Continuously loaded antennas, sometimes known as helical dummy loads, might do anything.

In theory, but this would be one of the great miracles of all time were it produced in spite of it being a very saleable product, some kind of trap vertical could be built which would more than likely look like a nine-foot whip with a funny box up 18 inches.

You may also get interested in 440 where the two meter whip will load nicely as a 3/4. Purely personal opinion: a 5/8 mobile is more mythology than reality.

It is really too bad that the whip comes close to resonance; otherwise you could simply build a little plate for the top of the spring and feed both together. This stunt is used on the Hy-Gain Hy-tower to feed 80 and 40 verticals from the same coax.

Jay, wade in on this one and make yourself a few centavos.

Whenever they do that, I always tell them that cell phones are free, from my employer, but I don't care for the biological effects of the RF energy. Now, about the Satellite receiver.....I tell them that I have five of those already.

A guy who can't follow a thread on a newsgroup is calling me clueless, now that is funny. By the way why is it all the pundits with nothing intelligent to ad feel that I must justify why the hell I am buying electrical cable at RS? Guys, because I F#$KING want to. Where is the rule that says you can't buy cable at RS? Like I said in previous post aren't they supposed to be and electrical supply store?. Anyway buying electrical cord at RS is not the point of my message.

Oh and by the way, I am now beginning to understand were it is they get these guys that work at RadioShack. I can see the want ad now "USENET posting a plus" :) I guess working RS would be a step up from "would you like fries with that? Sir." Right Kent or Eamon Skelton.

I could have mentioned that a 160m T antenna in your size backyard is usable on 136 KHz. Program TANT136 will also assist with design of the necessarily massive bottom loading coil. Also assist with estimating the effective radiated power. ERP could be as high as one solitary watt if you can find or construct a PA with 1 KW output. ;o)

But one watt on 136 will get you around hundreds of miles on slow morse. Propagation loss is measured in so many tiny fractions of a dB per wavelength and at 136 KHz there are not many wavelengths in 100, even a 1000 miles hop.

Anyone interested in 136 KHz (and indeed higher mobile freqs) should pay a visit to Dave, G3YXM's website.

I've found that given time...Usually not a lot of it and fold over really
equates to breake over/off.
It's happened to every antenna we've (both my wife and myself) installed.

If it was pouring rain, or a thunderstorm, I'd sure not stop to fold the
thing over.

The "on the glass" antenna would probably work fine. I had one on a Transam
rear window(hatch) which has the metalized tinting. I was just careful to
keep the mount form covering a solidly metalized portion. It worked just
fine.

Now that I have the 4-Runner I'm using the big Diamond mobile antenna and
the mag mount.
With that combination I have to be careful even pulling into my shop which
has a door tall enough for a motor home. I also had to alter my route to
the airport as there is a one lane bridge with a low overhead. (Already
broke off one antenna there on my wife's mini-mini van.)

I routed the coax down through the rain channel on the door behind the
dirvers door, then looped it back up and around the frame. Seems OK so far.
I may paint a piece of steel and install it on the rack mount as the roof is
very flexible...but again, I may just leave well enough alone.

Off Topic(s) - skip if you already understand Net Present Value.

"MiamiXJ" asked:
> How much can they really make
> selling cellphones and dishes?

Sorry to drift off topic(s)...

Did you notice that those two items mentioned are both associated with "recurring monthly charges". Coincidence ?

Pop Quiz: What is the ballpark ratio between a recurring monthly charge and its equivalent Net Present Value (immediate cash value)?

Answer: It depends upon your chosen interest rate (borrowing or investing), but typically a ratio of *about* 100 times.

Example: That bargain $20 telephone 'Caller ID' box really cost you about $600 NPV in recurring fees (assuming $6 per month, or $72 per year, year after year after year after year after year...). Add taxes and service fee increases over time and NPV could well be closing in on $1000. Yikes !

I'll bet those particular items (Cell Phones, Satellite Dishes) bring more than the usual 3 to 5% commission on the heavily-discounted selling price. You think that they're going to trip over themselves to sell you a $99 Cell Phone for a $5 commission ? It's the contract that you sign that makes them salivate.

Sorry to drift off topic(s) - but it is amazing how many people don't know this stuff.

J. Harvey
Ottawa

PS: Smoke ? Pack a day ? $4 a pack ? $120 per month ? $12,000 NPV !

"DJ" offered:
> A very long resonant wire has the virtue
> of gain, and isn't really directional unless
> you make it very high.

Gain without directivity is usually accomplished by having an omnidirectional antenna which has gain along the horizon like a flattened doughnut (it has directivity of course). Gain without *any* directivity must be a newly-discovered miracle. The two (gain & directivity) are closely related (loss being the difference between the two).

Perhaps our mountain-dwelling friend could take a rasp file up to the peak to sharpen the ridge to increase diffraction. :-)

There is always Passive Repeaters: :-)
http://www.valmont.com/communication/communication6.shtml

Seriously, single-channel NBS Yagis are pretty hot in comparison to any of the usual commercial TV or FM antenna. Add a hot preamp (not from Radio Shack, but from a V/UHF house with a fractional dB NF). If that doesn't work, then tell him to get a satellite dish.

Thanks for the reply.

You got me thinking; I added some wire to the power cord because I was planning on installing the unit in the trunk when the remote mounting kit arrived. The wire I used was enough to handle the current... only thing is I added enough to make the total length about 16 and a half feet... about a 1/4 wavelength on twenty meters. Oops, didn't think about that. Took the added length of power line off and things are MUCH better now.

I'd check the grounds of your transmitter and how the antenna is mounted. Clean the contacts at the transceiver and ground rod ends of the ground line. Is the distortion being heard at the other end of the qso? You should not need a coil balun if everything is grounded properly.

Good luck,

Bill, W4WNT

This sounds like EVERY Radio Shack that I've been in, from California
to Minnesota to Florida...it must be STANDARD training. You're right,
they DON'T know anything about electronics. And what's with asking for
your phone number, I'm sure many clueless sheeple freely give away
their telephone numbers...I always make one up. Then they ask..."Mr.
Jones?"...confirming the number, and I just look at them, in disgust,
and say YEAH! They know damn well it ain't my number at that point.

Then they try to make "feel better" by offering me a FREE GIFT, all I
have to do is plug this cord into my computer, install the software
(yea, right!), and log on to the net...I can just slide the infared
beam acrossed any UPC bar code and it will show the price...WOW!!!
Does this also give out my credit card, SSN, and/or even my REAL phone
number?

I don't buy jack-squat from R/S, unless I really need to.

I had good luck running an R5 on the house roof, about 10 or 12 feet above my station, with all the station gear nicely grounded to an 8-foot rod. Never a hint of in-shack rfi with 100 watts.

Thank you all for replying....

The Truck is a Volvo which apparently has a grounding problem when it comes to radios.

The CB is called "Ranger". My friend says that when he talks it sounds like booming and he can't Tx on USB (and probably LSB) because it's too incomprihansible.

If this gives you a better picture of what is happening then Please share your ideas.

I am greatful for this wealth of wisdom.

Sincerely

Mike.

2252. Antenna Expert Needed: Long Wire Question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-20 03:45:37 UTC
From: Levent <lsasmazel__NOSPAM@home.com>
Message-ID: <BlkK7.158995$ez.20322664@news1.rdc1.nj.home.com>
Source record: 154506

Hi,
After I move to the new home I did start looking a little bit gain. I can not put a tower and a yagi but I do have enough property to put a looong wire. Currently I do have a G5RV sitting on top of 75 feet long two trees. This weekend I put a 414 foot long wire SE to NW direction up 40 tp 50 feet. I did feed with a 450 ohm ladder line all the way to the MFJ Tuner. Result was a disaster. on the receive comparison it did perform 10 dB (59 vs 59+10 dB) less. I did test with some stations on 80 Meters (nearly 30 station all around the US) some 20 meter all of then said that G5RV vs Long Wire = -10 dB on the Long Wire site. Also there is a some level of RF in the shack (I know this can be normal because of the open line. But phones are also effected.) There is no RF burn only I can measure some RF with the filed strength meter. This must be very simple one line connected to one conductor from Ladder to the antenna but realty is it is not simple like I assume. What is my mistake ? Do I need to do something special to feed the wire? do I need a 1/4 lambda wire to connect other end ? I did check all docs (CEBIK,ARRL WEB, ARRL Antenna Handbooks) none of them shows an actual long wire project with this kind of info. I will appreciate all real life experiences.

If you like to replay direcly please use lsasmazel@home.com
Thanks in advance.

ABove is a much different case than off to one side at the same level. The
field strength below an R5 at 10 feet would likely be much less than the
level at the same level 5-6 feet off to one side.

I have three wire antennas that are all fed about 20 feet above the shack
and never a hint of a problem. Again, the clue is distance, I believe.

Reg wrote:
"Propagation loss is measured in so many fractions of a dB per wavelength and at 136 KHz there are not many wavelengths in 100, even a 1000 miles hop."

Careful now! You can measure cable attenuation in wavelengths because each mile of cable may have the same attenuation. Not so in miles of unguided radio propagation. At 136 KHz, the wavelength is about 1.4 mi, if I remember, and I`m too lazy to refigure it. Each wavelength of travel has a smaller attenuation, the farther from the sender it is. That`s because attenuation grows by 6 dB every time the distance doubles. Double distance grows from 2 miles, to 4 miles, to 8 miles, to 16 miles, etc..
Each of those distance increments has the same 6 dB reduction in signal level though the distance grows in exponential steps. While the first wavelength of travel represents an enormous reduction in signal level, the 100th wavelength of travel from the sender represents hardly any attenuation at all. This is why we can use radio to communicate with other planets when wires would have far too much loss even if it were practical to run wires.

Best regards, Richard Harrison, KB5WZI

My most successful squelch of RS droids is still, when one of them says, "Can I help you?" I point to an open piece of floor space, and say,

"Yes. You see that spot over there by the Sprint (insert relevant cell phone brand here) display?"

When he says, "yes," I respond with,

"Go stand over there until my car leaves the parking lot."

Generally applicable. Works every time. And because it's memorable, I don't have to say it more than once. Newbies are clued in right away by the experienced.

Unfortunately, 2M and 11M on one antenna is not likely going to happen.
However, you can do 10M and 11M on the same antenna. For 10M, use a 9' whip, and leave off the spring.
I have a roof-mount center-load with quick-disconnect mount, and a pair of antennas, one 11, one 10.

(and two glassmount dual banders, and a DF array, and a huge 2/440 super-gainer, and a scanner antenna, and a gps antenna...) I need a bigger car. :)

Hook up a dummy load, with a short jumper.
You'll get enough leakage to be copyable for maybe 10-100'
Check if the signal is ok then.
If so, it's very likely RF getting into the mic.
Your local CB shop should have some ferrite clamp-ons to help that go away.

Impedance in the power line will also cause big problems, though normally
that dosen't happen at 5W.

If the antenna mount isn't solidly grounded to the body, you could be using
the coax as the counterpoise, which isn't the right way to play, unless you
use a marine antenna, which is designed not to have a local ground.

The radiation pattern depends on the length of the long wire.
414ft is an end-fire pattern with very little broadside radiation.
If it is an end-fed long wire, you have unbalanced currents in
the feedline and it will radiate. You may be presenting your
tuner with an extremely low impedance leading to tuner losses.
I would suggest getting a modeling program like EZNEC so you
can determine what the actual characteristics of your
antenna are. The demo version of EZNEC is free from

2262. Re: Butternut HF2V + SGC SmartTuner = All-band vertical?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-20 05:58:45 UTC
From: David Cutter <d.cutter@NOSPAMntlworld.com>
Message-ID: <XcfK7.18775$9Q4.3138136@news2-win.server.ntlworld.com>
Source record: 154473

Hi Rick

Personally, if I had an auto tuner, I wouldn't bother with a tuned vertical at all. First the tuned vertical will have limited bandwidth, must be more prone to wind and wx deterioration and will be fairly expensive. Anyway, you should not attempt to "tune" an already tuned aerial. You cannot tune an aerial from its coax feeder. You'll help the tx get more power into the coax but that is not tuning the aerial. Hope I'm not teaching you how to suck eggs.

I think the Butternut has a "matching" length of coax (possibly 75ohm) before the feeder.

My solution would be to erect a non-resonant length of conductor (tube or wire or w.h.y.) as long as possible and fix it to the terminal on your auto tuner. Fit as many radials on the ground as you can to the earth terminal. The tuner will do the rest on any frequency within its range, right down to 160m.

Why non-resonant length? Then you avoid very high or very low impedances that the tuner would find difficult to cope with and become inefficient on one or more bands.

Yes, use the inverted V whenever the signal is stronger, but on the low bands in particular it may be advantageous to use the inv V on receive and the vertical on transmit. It will be quieter, more than likely.

Hope this helps

The easiest way to eliminate RF in the shack is to use a
balanced antenna that balances the transmission line
currents. A ground rod may or may not have much effect.

I want to get rid of RF in the shack.
I got the 8' ground rod.
What gauge of wire (insulated or not?) should I use and
how should I bond it to the ground rod?

2265. Re: 4 phased array

Newsgroup: rec.radio.amateur.antenna

Hello

For UHF I would have thought a small beam would be preferable to a phased array. These are used mostly at LF and HF because beams are so big. If it's speed of switching direction that you need, several fixed beams of 2 or 3 elements would have higher gain than the phased array and all you need is a coax switch. Millions of times easier than getting the bugs out of a phased array.

Hello Ian

You haven't told us anything about the bottom end of the aerial, which is just as important as the bit that radiates. ON4UN's book is amazing and one thing he constantly reminds us is the importance of the base radials and counterpoise systems.

If you can put down lots of radials do so. Then don't connect them to the tuner, just use them as an earth screen, ie to screen the aerial from the earth. Next make a raised counterpoise system of one or more wires up in the air and cut them to quarter wave if you can. According to Moxon they do not have to be straight, though ON4UN is a purist and advocates ideal systems because he has several acres to play with. You can add inductance to the centre point of the counterpoise before it gets to the tuner if necessary. It's all in the book. Don't worry too much that you cannot get the height if that's all that you can get, concentrate on the ground system and making an efficient tuner. That's another story.....

It can get quite tricky to model low frequency aerials and lots of stuff has been written about it, particularly modelling earth and radials close to earth.

Read ON4UN on LF antennae, it's worth every penny. HF Antennas For All Locations is also very good, but covers all HF.

Make it and play, have fun.

Good luck

It may well work better overall. The 10m tall "T" will act almost
purely as a vertical, and being short at 10m tall, the radial system
will be more critical than for the average inv L.
>
> The horizontally polarized radiation from a wire so low (10m) at 160

I've modeled them and the horizontal is almost totally canceled out if
using a symetrical T. I just threw his into the blender with the exact
dimensions and it had almost a pure vertical pattern. Very little
horizontal as far as the plot. Had a overhead null just like a 1/4
wave. The current on his proposed antenna is fairly constant up though
the vertical section. Would work pretty well IF he had a decent ground
screen under it. The inv L would probably be less picky about the
radials, but has a bit more horizontal radiation. MK

> antiRFI GFIs out there??

An R5 wasn't really designed to be ground mounted. It's a 1/2 wave design that was intended to normally be elevated. That may be part of the problem. if you got it on a mast up in the air, I bet half your RF problems would go away.
You've got one problem which is being in the direct field of the antenna. This causes fundimental overload problems. You could try a coax choke or two and see what happens to maybe help common mode problems on the coax shield. Couldn't hurt. I doubt grounding would help much unless it's at the antenna base, and like I said, the R5 wasn't really intended to be ground mounted.
It's a 1/2 wave design that doesn't really require radials to function. It should have a few short decoupling radials if I remember right. I don't know if improving the ground at the base of that antenna will cure your problem or not.
It might help, it might not...I think getting it up on a mast like it was designed to be run would do wonders to cleaning things up. MK

It is HIGHLY unlikely that a grounding problem would cause this. First, is he using an amplifier? If he is, be aware that it is illegal for use or sale. These amplifiers, being illegal, are generally made very poorly and can cause all kinds of trouble, such as the problem you describe. A common modification done to these radios by "CB techs" is to bypass the modulation limiter to make it "sound louder". This also causes more problems than it cures. It can easily lead to overmodulation and bassy, distorted audio. Couple this with the power mikes that are so popular, overdriving the input, and the thing sounds terrible. The Ranger radios of this type come into this country set up for ten meters. As such they are legal. They are then modified for eleven meters but are illegal to use on that band. A reputable, licensed tech would not touch a radio like this. He would be risking his license in doing so. To be so modified means someone has been inside that radio and if they did the usual CB modifications to it, that may very well be the problem. Try it with no power mike and (if it has it) amplifier. If it still sounds bad, it is in the radio. Finding a good tech to set it up right is a hit or miss proposition. If he does a lousy job, there is really nothing you can do about it but find some one else. You can't hardly go to the better business bureau and say "This guy screwed up my illegal radio". I'm sure much of this is not what you wanted to hear but I have had plenty of dealings with CBs and converted 10 meter radios and these are very, very common problems.

is it practical to have a 135' of wire end fed (inverted v) from the hot side of coax & have 1/4 wave radials for 40-10 mtrs attached to the opposite shield? the other end of the coax will have a tuner. i suspect this configuration could possibly be used on 80-10 mtrs?

I have a comet gp-15 tri bander set up at my location. It is rated I think at 150 watts. when I attempt to transmit around 147mhz at over 30 watts, the swr climbs up to about 3:1. Is this normal or do I have a problem? The antenna is 20ft about ground fed by 75ft of belden 9913. Is there any way to lower the swr or the antenna not radiating properly. Any help is appreciated .

2284. Info needed on a cross polarized design

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-20 11:02:41 UTC
From: Neoklis <neoklis@users.sourceforge.net>
Message-ID: <Pine.LNX.4.21.0111201301360.446-100000@up1000.home>
Source record: 154437

Hi!

I am looking for info on a cross (elliptic) polarized antenna design
which was used on Russian satellites since the first RS satellites.
I saw this design in a ham radio magazine that I don't remember now
and I would like to give the idea a try.

The basic idea in the design was to use two dipoles connected in
parallel and crossed at 90 deg. But instead of the usual 90 deg
electrical phasing produced with a 1/4 wave coax, it was produced
by making one dipole longer than resonance so it had a phase angle
of -45 deg and the other shorter so it had a phase angle of +45 deg.
The result was a 90 deg total phase difference between the dipoles
which gave elliptic polarization since the impedance of the dipoles
was respectively above and below the typical 70 ohms. Some residual
reactance was tuned out with a small inductor and this design gave a
simpler and lighter crossed-polarized antenna for satellite use.

Although what I remember of the design may be enough to get started,
I would like to hear from anyone who has more info or some practical
experience with this design.

My thanks in advance to all!

==========
My enthusiasm for extolling the virtues of low propagation loss on
longwaves led me into error. As you describe the dBs per wavelength
is not the same for every wavelength in the propagation path.
Nevertheless very low frequencies have very long wavelengths and so
there are fewer wavelengths between transmitter and receiver.

Thanks very much Richard for the correction.

The construction of 9913 includes an inner helical open path. This
opening can fill with water, even if the ends are fairly well sealed.
This construction makes for a partial air dialectric.
If cut open, this coax looks like an inner wire, covered with thin
plastic sheath, wrapped with a coil of the same plastic (spaced out,
with a gap). this is covered with another sheath, then the outer cover.
Water has bad, and unpredictable, characteritics, and can lead to many
strange symptoms. How long has this coax been up, and can you replace it
(at least temporarily) to make a 1:1 test?

A tale from the Dark Side...

About a million years ago I used to work at RS (I'm only bordering on being a moron, so I've moved on since then). This was well before the invention of Cell Phones and Satellite Dishes so I'm innocent of these latest crimes.

Anyway, this 'know-it-all' type walks in and asks to buy an "adapter". I ask him for further details and he gives me a difficult time and starts acting as if I were an idiot. After a short period of abuse, I walk over to the wall and pull one "adapter" from each inventory section starting with 15- and ending with 278- (about twenty different "adapters") and I bring them back and pile them up on the counter in front of him. He angrily starts poking through the pile but then calms down when he notices that every single package is clearly labelled "ADAPTER".

"Sir, would you like a spray can of 'Flux Off' with that ?"

RS was a pretty good job for a High School / University student - decent pay, interesting toys, flexible hours. Good deals on discontinued items (staff get first crack at them of course). Seemed to work out in the long run...

You need to make the path to the equipment a "high" impedance,
while providing a better return for the stray RF before it enters the
shack.
Assuming the problem is caused by common mode currents, add
a choke balun (ferrite beads over the coax) where it enters the building,
just after your ground rod. You can add a few counterpoises
on the ground (resonant 1/4 wires, not critical) and connected to the
rod with the coax shield (use an arrestor to do this task). That should
clear up the problem.

> wire project with this kind of info. I will appreciate all real life
> experiences.
>
You have a classic random-length end-fed wire antenna. I have a
temporary very similar wire (475 feet thru seven trees)and it works
quite well 1.8-29.7 Mhz. I simply feed the end of the wire right into
the shack and tune it with one or another of the MFJ tuners in their
"random wire" mode. There is no "feedline", it would be useless. I can
get a flat match on any band. The station is on the third floor and
there is no way I could come up with a decent earth ground but I did
string a single 150 foot counterpoise along a property line.
>
>
And yes, I have buckets of RF in the shack and it attacks any number
of the usual pieces of home electronics gear like the phones,
intercom, TVs, etc. Beads and RF chokes didn't do a bit of good, the
RF is everywhere. RFI nightmare. But I've worked a LOT of dx with the
thing including on 80 & 40 with 100 watts. I usually restrict my ops
to the wee hours which minimizes the grousing from the other dwellers
in the house. These long wires have weird multi-lobed patterns
especially at the higher freqs and there are "deaf" nulls in assorted
directions.
>
>
Some years back I had a tower-supported end-fed 135 foot inverted L
for 80 & 40 which also worked quite well. Perhaps better than my
current 475 ft. wire. In that case I cobbled together a
remotely-contolled tuner which was located about 40 feet from the
house and was installed in a wooden enclosure at the base of the wire.
I had a couple 8ft. ground rods driven right at the tuner which was
fed with coax via a low-pass filter. I didn't have any more TVI/RFI
problems with that configuration than I had with my 20/15/10m beams.
>
>
If I ever do another permanent end-fed wire it'll be remotely-tuned
some distance from the house with a short, proper ground like I had
with the old L but next time I'll also have a bunch of beads on the
coax both at the tuner and at the feed end of the coax and I'll locate

the low-pass filter at the tuner.

Use the heaviest you can find, and with as much surface area
as possible (many folks use the shield braid from RG-8 and RG-213
coax), I used 8 guage stranded, myself. Solder the ground connection
where you can, use a grounding clamp on the ground rod, use the
grounding terminals on the equipment.
My station happens to be daisy-chained, using shield braid
from RG-213 coax. At one end of the daisy chain, I've connected my
8-guage stranded wire, which is connected to the grounding rod just
outside my shack's window. Please understand, this is NOT a
recommended grounding situation. It provides a good ELECTRICAL
ground, but the RF ground is decidedly lacking (but in my operating
conditions, it doesn't appear to be a large factor). The station was
grounded in this manner because it was expedient and utilized what I
had at the time.
Since the original setup of my grounding configuration, I have
received a copper grounding strap, which I will eventually be
utilizing to ground my station. The grounding method then will be to
use heavy guage copper wire or coax braid to ground EACH individual
piece of equipment to the grounding strap, using as short a length of
wired as is possible. The grounding strap will then be connected to
at least two 8 ft (preferably longer if possible) grounding rods
located several feet apart, again using as short a length of heavy
guage wire as possible. All connections to the grounding strap will
be made by way of soldering the wires to the strap. This should
provide a superior electrical and RF ground for the station.
Understand, some grounding solutions are better than others,
but when it comes down to it all, ANY grounding solution is better
than NONE - providing it involves a good electrical earth ground.

Depends on the length of the coax, type of coax, and SWR.
A much better 130ft all-HF-band antenna is on my web site.

Marvin Rosen wrote:
"Is it practical to have a 135` of wire end fed (inverted V) from the hot side of coax and have 1/4 wave radials for 40-10 mtrs attached to the opposite shield?"

The army has a kit to make a similar antenna. They call it a vertical half-rhombic and elevate the middle by 30 to 60 feet. The kit is used with radios operating between 20 and 40 MHz. Length of the up leg and length of te down leg are each 2 wavelengths or more. They give an optimization formula.

A wire counterpoise directly connects both ends of the antenna. At the far end, the counterpoise is grounded and connects to the antenna through a 400-ohm resistor to make the antenna unidirectional. This resistor may be a dissipation line for powerful transmitters.

At the near end, the counterpoise connects with the earth again, and it serves as the ground connection for the transmission line. An unbalanced load near 400 ohms is presented to the transmission line.

Marvin`s 135-foot wire is not 4 wavelengths long at 40m. It is about one wavelength. The point is that the drivepoint impedance will vary and not match 50 or 75-ohm coax well.

It`s OK to omit the terminating resistance, but the earth connection at the drive point must remain else the transmission line becomes part of the antenna.

On the radio end, an earth connection is needed so that all doesn`t get too hot to handle.

Best regards, Richard Harrison, KB5WZI

I might suspect that running the ground in that manner could enhance the common mode currents, which would pass through the equipment, thus making the problem. I've always tried to establish ALL ground references at a common point before anything enters the shack; and this has always served me well. YMMV.

Levent,
Good luck with the longwire! (Personally, I have never been able to make one work very well.) The last one that I tried to make work eventually turned into a loop antenna which I found worked very well for most bands. I would suggest that you try the same thing. Connect onto the 'other' end of your longwire, bring the new part back toward the shack enclosing as much area as possible. Feed the thing with ladder-line from a tuner, and you will have an antenna that will work on all bands including 160 meters. On the higher bands (10-40m) you might be suprized at how well it does work! You will have a 'balanced' antenna doing away with most of the RF in the shack.
This really doesn't answer your question on how to 'cure' the problem with the long wire, but it is an alternative...
'Doc

Source record: 154450

Capra,
I won't recommend any particular brand of tower but
let me give you the following 'hints';
1. Always follow the manufacturor's suggestions on
the size of mounting pier, guys, and hardware.
2. The manufacturor's recommendations are the
MINIMUM requirement. Exceding the minimums
NEVER hurts.(Not doing at least the minimums
will always 'hurt', either ~you~ or your wallet.)
3. Do NOT hurry an installation. The old saying
that "haste makes waste" is true in putting up a tower.
4. If you are not sure/confident in any particular
part of putting up a tower ask someone who is competent.
The manufacturor, or commercial tower people are
good ones to ask.
5. Doing it 'right' the first time ALWAYS beats having to
re-do it later (and a lot cheaper!).

Not exactly what you asked, but very good advice...
'Doc

Hi Harv

At ONE TIME RS used to carry electronics, offered to order from an Allied catalog for you if they didn't stock it, even carried some great products. I still have some Ham paraphanalia from the good old days, the Variac they manufactured under the Micronta name still functions great.

At one time, everything in the shack was either Heathkit, Eico or Micronta(RS). Now it's Kenwood, Yaesu or gasp MFJ.

This would be trivial to model with the demo version of EZNEC.

Why not download it and see what happens?

Probably a lot. And each employee is required to try and sell what ever
corp. mgt wnats them to peddle...and if they sell one the get 'spiffs'
($5.00 or so.) Also did you know that if you have questions they have
answers? Sadly the answers never match the question!I.E.: Do you still
sell scanner crystals? Yes sir, check over in motorized race car
section. New Radio Shack greeting: DUH?

The fact is, there are very few retail stores left that get by, strictly selling small electronics parts, cable, wire, etcetera. This is especially true nowadays, with everything being solid state, surface mount electronics -- if it breaks, throw it away and get a new module from the manufacturer.

The way I look at it, the cellular phone and directTV sales are making it possible for Radio Shack to keep its doors open, and sell the small electronics parts nobody else purveys, anymore. The cell phones and directTV are subsidizing the rest of the store. If they didn't push the phones and TVs, the store wouldn't be there, to begin with.

When I go into a Radio Shack to buy some small part or wire or whatever, I smile and humor the sales people, and then go about my business and get what I want. Times are changing, and the RS people are just doing what they need to do to stay in business and provide you with a convenient neighborhood location for parts, gadgets and, yes, cell phones and directTV.

(No, I don't work for Rshack.)

Source record: 154461

Hello. I recently purchased the MFJ-1762 antenna. I am using the MFJ-906 antenna tuner with it. With the tuner on, I get a good SWR, but without it the SWR's are off the scale. The instructions included with it are MUCH less than thorough so I have some questions. The instructions don't specify how to hook up the feedline other than to "Connect each coax pig-tail to a feedpoint stud...". Should the center conductor of the coax be on a certian side? Should the lugs be inbetween the hairpin and the earth? Does it matter?

Also, I have tried fooling around with the balun (which you have to make - MFJ is too cheap to include one!). I have created an RF choke of about 5 turns of RG-8/U coax, but the SWR's are still off the scale without the tuner. Is there a commercially made balun that would work well with this antenna, containing the "pigtails" to connect to the antenna?

While you are at the 1:1 test, find a known good Dummy Load and substitute
it for the antenna. First test the Dummy Load under the same circumstances
at the rig, them move it down the line. Connectors and adapters can also be
bad or not properly installed.

How does the scanner crystal thing work? Does it go between the antenna
and the scanner? I have heard that some digital signals can be decoded
via this method. Is this true? Where can you get scanner crystals these
days if Radio Shack is not selling them anymore?

VHFRadioBuff,
It shouldn't matter which 'side' either of the two 'pigtails'
connect to, as long as the 'pigtails' make good connection to the 'hair
pin' match. I'm not sure what you mean by "[should] the lugs be
inbetween the hairpin and the earth?". The 'hair-pin' should connect
one half of the driven element to the other half, and I would assume
that the coax 'pigtails' should connect at each end of the 'hair-pin',
where it connects to the driven element halves.
The purpose of the 'hair-pin' is to match the input impedance of
the beam to the feedline impedance. If the 'hair-pin' is properly
adjusted, you should not have to use a tuner. The 'choke' you made
sounds like it should work fine. With the very high SWR your
experiencing, I'd take another look at the various connections,
something just isn't right. Something is either 'open' or 'shorted'.
Good luck...
'Doc

We had a few of them at one place I worked, so I found some software
that would just dump the straight value of the barcode, and used them
to get the tracking numbers off FedEx packages when checking parts in,
and to scan the part number barcodes for inventory.

Beats the hell out of trying to convince the boss to buy us a couple
of regular barcode readers.

Source record: 154383

If you're trying to make a decent RF ground, for a ground mounted vertical antenna, for example, an 8 foot ground rod is a poor solution in any case. This is because RF doesn't penetrate very deeply in soil, so in most of the HF range the majority of the ground rod is invisible to the RF. You're much better off placing a number of wires horizontally just below the surface. These can be any length. The effectiveness increases with length, but in general, there's not much point in making them much more than a quarter free-space wavelength or so long.

There are two other kinds of ground system you might be intending to put in. One is a safety ground for your AC power mains. This should be done according to your local electrical code. I recommend hiring or consulting a licensed electrician for this, unless you're entirely familiar with all the requirements of the local code. The other ground system type is for lightning protection. A lot of information has been posted about these on this newsgroup in the past. A search at http://www.deja.com will bring you a large number of postings on the topic.

Everything I read on grounding that mentions ground rods says to use ground rods at least 8 feet long.

Unfortunately, around here, we're lucky to be able to go down 3 feet without running into solid granite (that's why they call New Hampshire "The Granite State").

Any particular reason why I can't just use 4-foot ground rods, and more of them? Instead of one 8 foot rod, use two 4 foot rods or three 3 foot rods, etc.

Seems like an elementary question so I'm probably missing something....

Does it occur to anyone that these guys are just paid help, following instructions?
They are told, by tandy (who pays them) that they must ask for the name, address, and phone on each sale.
They are told to push certain products, either by tandy, or by their manager.
Either way, they are just doing their jobs.

Me, I find them handy for odd bits and pieces, when I don't want to wait for a digi-key order.
Maybe I'm blessed, but my local manager is a ham, knows his store, and his limits, and his people do too.

Source record: 154390

An antenna consisting of crossed and quadrature fed dipoles is often called a turnstile, and you might find what you're looking for by doing a search for this word. I've seen antennas using the technique you've mentioned described with a person's name, but can't recall the name and can't find references. It's commonly done -- you can see a picture of one of these on p. 22-18 of Walt Maxwell's _Reflections_ (first Ed.).

You could design one quite easily with EZNEC, even the free demo version (from http://eznec.com). There's a short manual section on modeling crossed dipoles (listed in the index under "Crossed dipoles"). Adjust the lengths of the dipoles until the currents in the two are in quadrature (90 degrees apart). Because there's no significant interaction between the dipoles, you could also model them separately. Simply adjust the length of a single dipole until the feedpoint reactance equals the resistance. Use this length for one dipole. Then adjust the length until the feedpoint reactance is the negative of the resistance, and use this length for the other dipole. The amount you have to change the lengths depends on the wire diameter.

Sorry I don't have any direct experience with this antenna. Keep in mind that the polarization is circular only directly broadside to the antenna. According to Fujimoto & James, _Mobile Antenna Systems Handbook_, the range of angles over which you can get reasonably circular polarization can be widened by making the dipoles in more of an inverted vee shape.

perfectly good question. yes, you can use more shorter rods and get the same effect, and in some cases better effects. space the rods as far apart as they are long. you can also drive longer rods at an angle or bury wires horizontally.

Does anyone know of a source for the nuts used on SO-239 bulkhead
connectors?
I'm adding lines to my window-box, and I'm going to need about 10 nuts.
I hate to buy the whole rig, and toss the barrels, just to get the nuts.

Also, any sources for low cost 9913 jumpers, about 25' with PL259's on the
ends?
(Or low cost source for 9913, for that matter, I have silver/tef Pl259s on
hand.
I'd use LDF4-50, but it's just too hard to work with in the shack. :)

In that case, punt.

You do what you can, and it wouldn't help to go deeper anyway, as granite is not a particularly good conductor..

More rods, shorter. Add salt.

If they are for lightning, you can trench them in horizontally as deep as you can go, laying them out like the spokes of a wheel. Also, you could probably use ordinary copper pipe and save a few bucks if you trench.

Why not use LMR-400? Better specs than 9913 and far easier to work
with. I think it's a bit cheaper to. More for less and easy too! :-)

Hmm.. I thought 9913 was the better one.
I'm open minded.
I have to run 25' to the window box, so I want to keep it low loss, as much as practical.
After that, they are LDF4-50 out to the mast.
I also have to come up with some 6' flexi jumpers to get around the rotor, haven't decided on that yet.

Brian,

You have solved your own problem with this, obviously, still I have had quite a bit of success with the wrist rocket by using a 1/2" steel nut. It is heavy enough to keep the line from curling or tang-ing and provide enough pull on the line to cause the line to come down far enough on the other side so I can reach it. I did have to paint the nut flourescent because one day I shot a line over an 80 foot oak and I couldn't find the nut! I kept jiggling the line because I thought it might've hung up in the tree. Durned thing was hanging right in front of me! It was late in the evening, so it wasn't all my fault. So I painted the nut and that solved that.

BTW, I can't see paying so much for one of these things because they are so cheap to make for oneself.

Go to

http://www.timesmicrowave.com/products/commercial/index.htm

and choose the "LMR selection guide" where you view a comparison to
other cables.

I have been using LMR-400 for a couple of years now and am quite happy
with the stuff. Low loss and easy to work with.

My experience with Texas Towers out of Plano, TX

Hello all. My Name is Brent and my call is N9BC. I would like to tell everyone about my experience with Texas Towers. On Monday 10/15/2001 I decide to buy an ICOM 706mk2g. After scouring the net I found that Texas Towers seem to beat everyone by about 30 bucks. So I went and gave them a call mid afternoon to place the order. Someone picks up I believe his name was Brian. He was very pleasant to talk deal with. The deal they advertised was $869 with free shipping sounded like a good deal so I opped for the over night shipping for an extra $33 still not a bad deal! So I finished up the order and hung up.

All night and a good part of the next morning I was all excited about getting the rig. About 9:30am it gets here WHA HOO!! Open the box up start taking out the parts to the radio. So far so good next the rig. Take it out of the plastic what do I see a BIG black bloch across the LCD. I was horrified! I couldn't believe it. After a few choice words out loud. I called Texas Towers to let them know. They asked if the box was damaged it wasn't so they said it must of happened at the factory. So he said ship it back and they will ship me a new one. I said I guess so. So I hung up.

I sat there looking at the broken radio and decide to call them back to see if they would overnight me a new radio if I overnight this thing back. Got Brian back on the phone he said he needs to talk to the boss. 2 sec later he said sorry no can do. I'm like what? You are kidding me! Nope if you would like it shipped back to you overnight you will have to pay for it. So I said ok thanks and hung up.

Off to UPS I go. I get there and ship the thing back to them overnight. So that is another $33. I get to work a few min later. Sitting at my desk festering about the whole deal. I call them back and ask for the manager. He gets on the phone. I tell him the whole story and he said no sir we can't do it we don't make very much on the radio that is why we are the cheapest on the net. I said if you ship it back to me overnight I will do business with you again in fact I will place an order of $400 today with you. Still he wouldn't do it. So I do the good ol' saying I will never do business with you again. And hung up the phone. Boy was I mad! Now it is Friday and still no radio and I really wanted it for the weekend. So I broke down and told them to ship it to me overnight with Sat delivery another $45 for shipping. Got it on Sat as I was on my way down to AES to get the rest of the order. I sure wish I would have just bought it from AES to begin with.

Anyways I would never recommend TEXAS TOWERS to anyone. So beware they have no customer service what so ever! CS is very important to a business

apparently they don't believe so.

Thanks for reading,

Brent

You have almost exactly described the Barker and Williamson antenna
model
AC 1.8-30, which is (or was) sold as a 160 meter-through-10 meter
no-tune antenna, and which certainly wasn't 4 wavelentghs long at its
lowest frequency.
It used as balun at the feedpoint, a counterpoise wire lying on the
ground between the feedpoint ground and the terminated end ground, and
is elevated in the center by 30 to 40 feet. I used one for some time
mounted on a building using, instead of the counterpoise wire, the
perimeter metal flashing on the roof which had each section fastened

together with screws. We used it on a 8 mHz HF net and alternately on ham radio net frequencies and it performed acceptably for the purpose. I found it to be the rough equivalent to the B&W T2FD. We also had one of those installed. Sometimes we needed to work the 8mhz net and the ham band nets simultaneously.
I just noticed that B&W no longer advertise in the ham radio magazines as they have for so long. They are not listed in the advertiser's index of either QST nore CQ. I wonder if they're still in business. If not, it was a very long and very good run, they've been around somewhat longer than I have.

Here we go again... SWR is NOT the ratio of power sent to antenna and
power not accepted and sent back. Let (P+) be forward power and (P-) be
reflected power. SQRT is the square root.

SWR = (SQRT(P+) + SQRT(P-)) / (SQRT(P+) - SQRT(P-))

or maybe easier, the reflection coefficient magnitude (Rho) is
equal to the square root of (P-/P+) and then

SWR = (1 + Rho)/(1 - Rho)

Source record: 154402

Hi--

I designed that antenna for MFJ about 5 years ago for MFJ, so I'm familiar with it.

1. The driven element uses a hairpin match, so it doesn't matter which sides the braid and center conductor go to. Keep the leads as short as possible, though.

2. It would be very hard to wind a 6-M balun with RG-8. Try feeding it with RG-58 or RG-8M and run it down past the rotor before transitioning to RG-8. I used two ferrite sleeves for a choke (#43 Mix, Amidon 2631540002). Couldn't convince MFJ to include them with the antenna. The coax balun will work fine, but use smaller coax.

3. Check your antenna's boom insulators and make sure they're hard plastic. I recently heard that MFJ sold a batch of these antennas using rubber grommets for Dirven Element insulators. If you got these, call up MFJ and complain.

The antenna should have very low SWR if it's working properly.

Good luck and 73

Rick K!BQT

Yes you can use an 8 ft ground rod.

Dig a trench 8 feet long, 18 inches deep, lay the rod along the
bottom, throw in some buckets of water, turn the soil into mud,
fill in the trench, tamp well down. By the way, don't forget to
attach a copper strap to the middle of the rod before filling in.

It is just good salesmanship... that's why they should have overnighted the replacement. If the customer isn't happy, ain't nobody happy. That is what I learned in the retail business some years ago.

The only reason eight-foot ground rods have acquired a biblical-level
following within ham radio is because it's hard to find shorter rods.
Hangover from the National Elecrtical Code which has little or nothing
to with the physics of ham radio.

okay volvo was very poor for grounding so a new ANT system like I said is the first start (I have found a good ant can over come a low wattage everytime) have the radio checked on a watt meter Rangers have a set output if it is changed from the box specs then someone chopped it (I can name stores in every other state that don't do good ranger work) To be honest the best system I found was a Cobra 29 LTD with the finals replace by a 1969 final and the audio limiter cliped...NO POWER MIKE only a noise cancelling mike...and here is the biggest trick...the dead key was set to 2 watts (half the legal) this allowed the radio to run almost 45 watts peak and with the ANT system I had at that time 25 mile range dependable in motion.

From indications your friend may be better off selling the ranger (it sounds like a hack job) and getting a newer radio. Best one I use now is a President George (it is made for europe but an international config (WITHOUT OPENING THE RADIO push button programming) will allow 340 channels and a 30 watt peak with 16 memories on AM,FM,USB,LSB. Remember that while you have the channels that you may listen but don't transmit....and use a noise cancelling mike in the semi never a power mike it distorts the signal.

Reminds me of an interesting and colorful character I frequently worked back a few years ago on 160 meter AM. Now a SK, he was a Signal Corps colonel in WW2. I had seem him numerous times at hamfests before we ever got acquainted. He always had a gawdawful table load of junk parts for sale, some of which I always seemed to need. He lived about a hundred miles from me and always had a meter-bending signal down this way on his BC610 and "tuned wire" as he called it.

Once as I was passing through his town I stopped in for an eyeball QSO, to snag a cup of his coffee, and to look over his rig and that "tuned wire". It was simplicity itself. A single wire led from the output jack of the BC610 about three feet to the wall where he had mounted a fairly large air variable capacitor and an RF Ammeter, and from there it was 'random wire' all the way. Never more than 12-14 feet off the ground, it went down across an open field, where he and his son stored all the junk Pontiac GTOs and other models they were restoring along with with the parts cars, and into the woods. I'm sure he had the 610 grounded somewhere, somehow, but he didn't mention it and I didn't notice. He didn't know exactly how long the wire was, just 'random', but it looked like no more than a couple hundred feet or so. To tune the antenna he'd merely dump the RF output of the BC610 into the wire and tune the variable cap for maximum RF current indication. And it sure played well. The GTOs probably helped.

There is an article on ARRL site. Hints and Kinks for grounding, I think.
Referred to an article in Signal Magazine. Experimenting done by the
military found that four rods(hooked in series) driven one or two feet in
the ground were sufficient. hard copper tubing would probably work.

I ordered a radio from Gigaparts. They said the radio would be shipped the next day. Two days later I check with them to get my tracking number and the radios didn't come in so they could ship them to me. They offered to send the radio out 2nd day UPS. Which the shipping department screwed up on and sent them ground. I called them back and he offered to send me two radios over night and to just refuse the first two. Would most companys do that??? The guy I deal with promised me a deal on my next order to make up for the problem. About a month later I ordered another radio from them. The man I deal with wasn't in so somebody else took the order to give to him since he didn't know our deal. Somebody screwed up the order and they sent it out COD. After they tried to deliver the radio COD I called them back. They overnighted a check to pay for the radio. They have screwed up twice but have done anything the could to make it right.

Actually, their web site is still up, http://www.bwantennas.com/ in six languages, yet. And they list dealers all over the country/world. Maybe they've just cut back their ad budget for the rest of the year...

I have to second that go with LMR400 I just ran some and some 9913 and the LMR was a bit cheaper and easier to work with. On paper it seems a bit better but I doubt there is much real world difference between the two.

Try this place they have decent pries and good service

They would have kept my business if they would of even met me half way on the shipping. is it too much to ask for? Even if they didn't make a hugh profit on the last sale I'm sure the would have made it up for it over the next few months from me. Now I don't mind driving down 1 1/2 hrs to AES. In the last month 1/2 I've sent down there a good $700. Just for grins I ask the salesman at AES if the same thing happened to me with them would they of shipped it back overnight. He said of course we would have. We shipped a defective product. Sure sounds like they have their act together.

I dont want this to turn into a big flame. I just wanted people to hear me about my experience with Texas Towers.

Did you know (at least for corporate stores) the employment application
actually states that RS can fire an employee immediately for any reason
or no reason, and by the same token, the employee may quit with no
notice at any time for no reason or any reason.

This is actually a place I'd consider working, as I like radio, but I
don't want to be a pushy sales droid that must always be on the hook to
keep management happy.

Bob, I regret that you have had what, from your viewpoint, appears to be
lack of support to the customer.

As another viewpoint, I have been dealing with Texas Towers virtually since
they went into business. I have purchased over 20 radios from them plus
uncounted antennas, monitor receivers, misc. equipment, HTs, cables, power
supplies, etc. etc.

Gerald Williamson and his son Matthew are as honest and forthcoming as you
will find anywhere and they have always done their best to ensure that I
received value for my money and a smile to go with it. Trades have been
fairly valued at both ends. I bought my most recent radio from them - an
Icom 756PRO - and intend to buy my next radio from them, whatever and
whenever that will be.

Sounds to me like there might have been some additional considerations in
play here that your account did not include.

I don't use 8 ft ground rods here. I'm too cheap to pay for the
things. I use mainly scrap copper tubing of varying lengths that I
stick in the ground and tie together. I get loads of scrap copper
tubing free. Also it doesn't have to go downwards, they can go
sideways under ground and still work. Way better than nothing anyway.
Myself, I'd rather have a few shorter 4 ft pieces tied together than a
single 8 ft rod. I don't see any harm in it anyway. I've taken direct
lightning hits on them, and they didn't complain about lack of depth
at all. But I do have good soil conductivity, and was also tied into
the water pipes. MK

Nothing unusual about that. Someone is hired to do a job. It's managements job to set the standards of how that job is to be done. If they don't like it, out you go. I assume that you don't have much work experience.

For a while, Radio Shack had a branch called TechAmerica, which then changed to RadioShack.com (though it was a so-called brick-and-mortar store) that was pretty good. While I was living in the Phoenix area, I used TA/RS.com frequently. Found a lot of hams working there, no inane salespeople (not at least over by the parts/cable/tools counter). Too bad that retail concept failed to flourish (or did it fail outright? I don't know, I am far from AZ these days). It is a good day when you can walk into a retail store, and be confident that they have in stock, on the actual, not virtual, shelf most values and types of small parts (even a fair selection of ICs, RF power xstrs, and LV xfmrs., in stock, amazing. . .), common or no, as well as decent tools and supplies, and can actually *find* the correct items in less than 5 minutes (or before you do. . .). No such thing anymore (in Seattle anyway) as a retail/consumer electronics parts store with a (semi) comprehensive inventory on site, alas.

It's called "at-will" employment, and is gaining ground all over the country. It's a nice way that employers, especially large corporate employers, to get off the hook for canning people for being gay, a union member, muslim, etc. It was part of a package of laws euphemistically known as "right-to-work" (brought to you by the same lexicographers who gave us "trickle-down," "supply-side," and "acceptable collateral damage") enacted in the 80's and early 90's. Common as (acid) rain these days. . .

I see. So is there any document I can read to understand this better and why the SWR meter reads differently at higher power. Thanks.

drive er in at up to a 45 degree angle, it will go as the rod will tend
to bend and follow what's blocking beneath it. we constantly drive rods
in this way up here with a 20 lb sledge hammer however be aware that if
the rock underneath slopes up you may end up getting poked in the ass by
the rod coming thru the surface behind you been there done that

because of shear numbers the middle class must carry the majority of the tax burden. a lot of people make good money in the US; however, many do not know how to save effectively. sadly, many high income earners could only survive a couple of months if laid off. hey, weren't we talking about RatShack :p.

Add to that, a good way to get rid of the lazy shithead leach employees that managed to get hired on that have no intentions to fulfill their end of the bargain and perform work/job assignments. Or are totally incapable of performing the work they said they could do.

2381. Re: Justice AM Antenna-anybody got one yet?

Got the antenna-here's my report for anyone interested in AM listening:

Wow! Verrry impressive. It took a little while to find my "sweet spots"
but once I did-holy cow! Listening from Chicago, my first evening I got
stations from New York, Toronto, Boston, Nashville, Denver, Atlanta,
Pittsburg, Louisville, Detroit, St. Louis and others that I didn't
listen long enough to find out where they were coming from.

I mounted the antenna by a window and ran the optional 25 ft cable
right to my little bedside ATS-909/DX398, thereby eliminating the need
to hold the radio by the window forever! Fufilled my expectations and
then some! Totally satisfied.

Since the actors union pretty much killed internet streaming in the
States, this is the way to go!

Thanks a ton Justice and CCrane!

If you're interested in you can get one from here:
http://www.ccrane.com/am_antennas.asp

Note: I do NOT work for CCrane or Sangean.

> retail/consumer electronics parts store with a (semi) comprehensive
inventory
> on site, alas.

What you mention has been brought upon ourselves by ourselves. Consumers have demanded (voting with their purchasing dollar) the very lowest price on items. The only way retail could do this is continually decrease employee wages/benifits (near minimal wage and thus, minimal qualified employees working there) and in recent years, even fewer store clerks/floor people to assist the customer. We have traded service for lower price. We should be happy.

I wouldn't think so since its a short-coming of the product. The ones I have seen that behaved like this were really cheapo units and I suspect that it was no more than bleedover between the forward and reverse sensing elements. The question remains open at which power level is the reading most accurate? I would suspect the reading is more accurate at lower power levels rather than high for the reason stated above. I used to have a cheap Calrad meter and such was the case with it, even at HF, although it was rated to 144 Mhz.

2384. Re: Can't use 8 ft ground rods, now what?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-21 12:35:44 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <9tg755$ee6$1@plutonium.btinternet.com>
Source record: 154334

In general, it is the longest dimension of an electrode which most influences resistance to mother Earth. The diameter of a buried wire has a relatively minor effect. Two rods close together are hardly any better than one rod. The full benefit of two rods is not obtained until the rods are spaced apart more than 3 or 4 times their depth.

A single rod is of little use at RF unless immersed in sea water when a length of only 12 inches is excellent.

Curiously, a thick-plastic insulated wire may have a lower RF earth loss resistance than the same wire when bare.

Programs RADIOETH (RF) and EARTHRES (DC, 60Hz) model the behaviour of shallow-buried electrodes, wires, plates, arrays of rods, sets of radials and describe simple methods of measuring soil resistivity (1/conductivity). But there's never any need to know resistivity accurately at RF.

Soil permittivity plays a significant part above 5 or 10 MHz. But that's another matter and, anyway, at the higher frequencies the types of radiating systems tend not to make use of ground electrodes.

Thank you for your reply. I will fashion a new RF choke out of RG-58 cable. How wide should the choke's diameter be? The instructions say to make it from about 5 turns of 6' of coax. The grommets that were included were plastic. The leads (or "pigtails" as they are called in the manual) are short, about 1 1/4", as specified in the instructions.

There is just too much info to have it all in one place. The reason for the differacne in the way a swr meter reads at differant power levels is that the diodes used behave differant at low power levels. On most of them there are 2 diodes , one is used for forward and one used for reverse. The reverse diode will not have enough voltage developed across it to act the same as the forward diode at low power levels. Look up square law detectors for more info on this. A true driectional wattmeter needs to be used if the power level is much less than 50 to 100 watts to get an accurate swr measurment. The swr can then be calculated from the power forwarda nd reverse. Even then it is beter to have two ranges with one about 10 times the range of the other.

Much of this has been discussed here in the past. It is just part of the many things that are learned by being a ham for many years. The books can give lots of theory about how things work but there is enough differance in the real world that you just have to learn over a period of time how things really work. Elecrtonic circuits can be calculated to many decimal places but if you calculate a resistor of 1234.222 ohms and try to buy one you will have to setle for one of probably 1200 ohms standard value and it can then vary asmuch as 5 to 10 percent depending on the manufactoring tollorance.

As for your antenna you need to measure the swr at several frequencies in each band. Then you can find the frequency of the lowest swr and if needed make adjustments from there. It may be the antenna just does not have enough bandwidth to give a low swr from the lowest frequency to the highest frequency in the band.

It is not 'bleedover' but the way the forward and reverse diodes conduct at low power levels. Normally the higher power level will give a more accurate reading on the cheap meters. Most of the vhf meters can be uses on lower frequencies if you can run enough power to the the meter to go to full scale in the forward direction. The problem is that sampling porton of the segment in the swr meter is not long enough to pick up enough power to use it on the lower frequencies and if it is made longer then it will be too long in terms of wavelength to work at vhf.

That's standard in TX. IIRC, the only jobs you can't walk away from
at any time, without notice, are certain emergency services positions.

But the rules do work both ways, and a friend of mine exercised her
option to bail out of a job that had turned very ugly, with no warning
to her employer and no consequences -- near or long term -- to her.

yeah, right

I hear that line all the time in the transmission business, usually from big companies:

"Give us a price break on the first one and we'll send you all our business"

then, guess what? they conveniently forget that the first one was at a 'special price' and want that price for ALL of them.

sorry, man, you got what you paid for.

My experience has been all good. I went there to buy 12ft sections of
aluminum tubing for a 40m vertical. Even though it reduced the amount
of the sale, Gerald pointed out that using 6ft sections would reduce
wind load (given the same size bottom section).

Iron Head wrote:
"---and why the SWR meter reads differently at higher power."

All measurement devices have error. The question is: How much?

If an SWR reading is noticeably a function of power level, the instrument error may be excessive. On the other hand, the instrument reading may be correct and the antenna system may have a defect. Sort it out by using known SWRs to check the instrument and using known instruments to check the SWR.

Best regards, Richard Harrison, KB5WZI

Source record: 154344

vtail,
For what it's worth...
1. A number of short rods connected together is better than one
longer one.
2. Wire radials are better than ground rods, in most cases.
3. The more 'metal' in the ground, the better off you are.
4. Don't use un-tinned copper braid for grounding, inside or
outside. Depending on your weather, it deteriorates quickly.
5. Using salt on/around your ground only contaminates the
the water table, kills grass, disipates rapidly. Waste of
time considering the benifits.
6. Consult the National Electrical Code for RF grounding. You
might be suprized. (If you have RFI complaints conforming
to NEC cetrainly is in your favor.)
7. Using fences common to a neighborhood, or pipes in a common
water system is bad news (no matter what the books say).
They become a part of your antenna system, and having a 'part'
of ~your~ antenna in your neighbor's yard/house is NOT
something to be desired!
'Doc

In <W3FK7.18880$3s2.1076661@typhoon.kc.rr.com>, "Brent" <brent316@yahoo.com> writes:

Hi Brett..

>My experience with Texas Towers out of Plano, TX

.. Sad experience snipped .. but not in jest here .. just for space

>Brent

>N9BC

I have known Gerald, his son, daughter, and the group for MANY years. This family is a top notch very capable and very sincere group. I've dealt with them in person at the store, in person at the hamfests, by phone, by mail and via shipments, you name it; we've done business together. I've sat down to dinner with the man in Richardson, even been invited to his antenna farm out Northeast of Dallas.

That full sized three element rotary array up there at 190-odd feet run by a large prop pitch that uses 105 feet of Rohn 25G for a boom and 4 inch irrigation pipe is a beautiful job, But you have to know a little more about it to really know about this man and how much respect most people I know have for him. It's the SECOND time that array has been put up there Brent.

The first time it went up, Gerald had help from the local crew. As you can imagine, playing that game with 130 foot elements and the equivalent of Rohn 65-G for the tower isn't exactly lightweight stuff. And the man on top the stack *IS* the boss on tower work like this, if you've ever been there Brent, for good or for horror. Things do go wrong,,,

As I understand how it happened, Gerald got in trouble with the last Phillystran guy and didn't have the right thimble bolt to attach the guy run to the tower top. So he used a Rohn 55G tower leg bolt on what he told me was a 'temporary' basis, just to get down the tower and finish that day, Everyone was dog tired, enough is enough. I'm sure from your post that you know the feeling...

But he forgot about going back up that 195 feet to replace that substitute bolt with the right one. And Texas isn't very nice weather wise at some times of the year. Along came that massive frontal passage and .. that tower leg bolt snapped and down came the whole thing, tower and all. I'm sure, from your post, that you know the feeling, maybe from a different perspective, but you do have a way to relate to this.

If you happen to be on the place, there is a section of tower still plugged into the ground at a crazy angle where it augered in. Gerald said he left it there just to remind himself of his mistake. And, yes, that whole thing went up again a SECOND time. But not quite so much in the grand show as round one.

For, as I understand it, in 'payback' for all the wasted time and effort Gerald caused the local crew, by not going up and taking care of making it right the first time, as I was told, he, with only the help of one other feller on the ground, put round two up all by himself to make it right with his own insides for what he caused on round one. This is the kind of man and family you are dealing with Brent. He is a horribly honorable man and a prize contributor to an awful lot of people in this hobby Brent.

You need to know a little more about the profitability in business, in general, before you can fairly judge some things like this. Most people do not know that over the last 50 years or so in the USA, the average bottom line profit for all businesses is only about seven cents (7 pennies!) on the dollar at the end of a year. That includes GM, IBM, Ford, a whole bunch of dot.com's that lost tons of money, mom and pop grocery stores and folks like you and I and Gerald! It's rough out there Brent; bottom line on a $600 radio isn't over $40, if that. Ten years ago when money meant a little more something, I knew that Gerald needed an average of over $8000 a day on that 1-800 watts line, just to break even! And that's not to turn a profit, just a wash.

It takes about $350,000 worth of equipment sales just to pay either someone else or yourself only $24,000 a year, Brent. Oh sure there are great deals and high proced time and all that. But bottom line is that the old interest rate figure on the US Government long bond is there at that rate for a real reason! Free enterprise does have it's rewards, but Socialism is right there just under it to always think it can do it better, friend Brent! Huge grin!

More important, you have to realize the reverse is true! If you lose a $600 radio and don't get paid for it at all, at seven cents a dollar net to the bottom line, you will have to sell almost $9000 worth of new sales just to break even with what was lost! That $40 loss taken three times in the shuffle on your deal would mean someone has to do almost $2000 in new business down there just to pay for it.

In the average business here in the USA, even if a minimum wage employee poofs away one $7 hour or so, it takes $100 through the register just to recover that, what at first, looks like such a trivial deal. Yeah I know, you'll say you don't believe all this with what doctors and lawyers and Indian Chief's all make and so on, but, sadly, it is true.

A whole series of events in the world that are rather scary are teaching this lesson of bottom line profitabilty to a lot more folks right now. It is so easy to not realize just how thin the ice all humanity skate on; is. Even though the numbers are in the billions, the percentage of what's left over is still the same, still the same.

As far as I know from many years of dealing with Gerald, this man has done everything possible to put back every cent of what his family has ever managed to wrench out of life, back into something that will bring a better day and a better world for everyone around them. And I used the proper term in what it has taken them to stay functional.

I had a similar experience with a brand new FT-1000 I bought from him! It had a dead output RF amplifier section on arrival, right out of the box! But knowing what I've attempted to convey to you above, I gladly paid for the shipping and all, both ways. I found, as I usually do, that, as it has been long 'Fabled' grin, even the smallest kindness never goes un-noticed. He's long since contributed back to me far more than that I spent to help him.. Far more...

--> Sleep well; OS2's still awake! ;)

Brent,

I would say since you paid for an icom 706 on your door step the next day, you should have one as advertised.
I would think they should have refunded your shipping cost, since you had to return the radio or at least sent the new one overnight at no cost to you.
I've been a ham for 8 years and have had this type of experience with most of the ham stores. They expect the consumer to bend over at the drop of a hat.
Thanks for the heads up on Texas Towers.

Don't bring up Sears, they have an unspoken policy to try and destroy the families of those that do not hold Sears credit cards nor even shop at Sears by placing fraudulent data on their credit reports, then taking their good old sweet time in seeing that it is removed (after the damage is done).

Vtail wrote:
"Any particular reason why I can`t just use 4-foot ground rods, and more of them?"

If you use enough short ground rods, you will get a better ground connection than a single rod can produce.

HL&P, the electric company here, says it prefers a driven ground rod to other grounding systems, though NEC requires that the "interior metallic cold water piping system be bondeed to it.

NEC requires grounding the electrical service to a "metallic underground water piping system" if available. A driven ground rod is an acceptable alternative.

In HL&P`s grounding practice, length of ground rods is unspecified. HL&P probably doesn`t want to be required to dig or pull up ground rods to show that they are as long as they said they would use.

HL&P`s preference of ground rods is clear. They use plenty, and they butt-wrap their poles with ground wires. Their number of paralleled ground connections is almost countless.

For r-f, it makes little sense to penetrate the earth`s surface any deeper with a ground rod than most of the r-f does. Soil skin-depth is deeper at lower frequencies and higher soil impedance.

Ed Laport has an appendix to "Radio Antenna Engineering" for skin-depth. Picking a soil conductivity of 10 to the minus13 e.m.u. :

10KHz...50m
20KHz...35m
50KHz...20m
100KHz..15m
200KHz..11m
500KHz...7m
1000KHz.5m
2000KHz.3+m
5000KHZ.2+m
10MHz...1.7m
20MHz...1+m

Another factor Ed stresses elsewhere is that ground conductors are useful for r-f to the extent they conform to the direction, path and extent the current must take. Radials under a tower are in the path of current to the world at large. Interconnections between radials encourage useless and lossy eddy currents. Of course, a solid-copper

sheet under a tower is terrific because it represents an infinite number of radials. That would help shield the earth from current and copper is less lossy than soil.

Best regards, Richard Harrison, KB5WZI

Doc, W5LZ wrote:
"Don`t use un-tinned copper braid for grounding inside or outside.
Depending on your weather, it deteriorates rapidly."

My inference from the above is that tin might be needed to protect copper. It is used on automobile battery ground braid isn`t it? Yes, but it is more subject to acid exposure than it is in other venues.

Tin is used to protect iron and steel from rusting. We have tinned cans. But, copper is a different metal which gains a sulfide or an oxide that usually protects it from further corrosion. Most iron alloys aren`t protected by their rust from further rusting.

Copper rarely needs protection. Copper is used for roofing. Centuries-old copper roofs aplenty are keeping castles and cathedrals around the world nice and dry.

I'm getting a little off-topic, but here goes:
I went through my credit cards a few months ago and cancelled all the useless ones (Mervyn's, Wards, Sears) that I don't use anyway. They are very surprised when you call to cancel - they are used to complaints and requests to open accounts or increase credit lines. They act as if it were a sacrilige to cancel a credit card!

Radio Shack reminds me of a shoe chain that I once worked for as a second job while in college - minimum wage, no training, maximize profits, 99% imported merchandise of inconsistent quality, high mark-ups.

Ron H wrote:
> Does an electrically short antenna look "inductive" ? ....Please explain.,

An electrically short monopole or dipole exhibits capacitive reactance.
A 1/4WL monopole or 1/2WL dipole exhibits no reactance at resonance.
Between 1/4WL and 1/2WL a monopole exhibits inductive reactance.
Between 1/2WL and 1WL a dipole exhibits inductive reactance.
Monopole statements assume a proper ground plane.

do a little thought experiment. Play like an electron at various points on
a dipole as the cycle goes up and down. Wire a virtual ammeter to the
feedpoint and a virtual voltmeter to the tip to the feedpoint. Start with
resonance and work with too long and too short. Remember electrons repel
each other as they gather at the tip.

You will find that a short antenna is a capacitive load and a too long one
an inductive load. The idea is that current and voltage do get out of
phase, current leading in the short or capacitive load and lagging in the
long or inductive load just as they do with lumped values.

The proof is left to the student :-)

Extra long tie off rope on the ends...just let it down to work on it and then pull it back up. Yes the rope will grow into the tree if you don't move it at least a couple of times every year. Ropes also rot.

Another issue is that trees move, so if the installation is too tight, it might snap the antenna wire. I've seen installations solve this issue with a pully and bucket of rocks...as the tree moves with wind, the rock bucket goes up and down...heavy enough to keep it tight, but enough play to keep it from breaking as the tree moves.

For permanent installations, add a tilt-over base onto your tree. <g>

I've seen a thing called a Hazer for Rohn towers...need one of those for southern pine trees, now.

Nothing wrong with 6 guage stranded, that works. Some people prefer braided straps or flat tape due to surface area in contact with ground, but I don't think the average ham could tell the difference.

A little corrosion might actually make a better bond, but don't let it corrode away! Corrosion does add to resistivity on the conductor, so I would let it set several weeks in the open and maybe with some salt water rinse to help it bond real good, then clean the outer surface well, and coat it with UV resistant rubberized coating like Plasti Dip Spray On.

Of course, I didn't do that with mine...I bonded the clamp and added a couple of small hose clamps for additional bonding, and then hammered the whole thing into the dirt below ground to keep it out of the way of my lawn mower. Works fine. Probably will dissolve in 30 years instead of 40, though..

Capra wrote:
"I have some 6 gauge stranded copper wire. Is that good enough for ground wire?"

My local power company is silent on solid versus stranded wire. It`s reasonable that they require equal ampacities so that their statements are applicable and their requirements are met.

The power company does make a reference to aluminum wire. It is : "An aluminum neutral wire must be insulated. I speculate that is because the aluminum wire might otherwise be more susceptible to damage.

The one place where a coating or other substance may be used in a wire junction is between aluminum and copper wires or fittings. It is unusual between junctions of similar metals.

In its service standards, my power company says:
Grounding Conductor:
Minimum of #6 CU securely fastened, or #8 armored (or in conduit).
Ground Clamp:
Manufactured and approved for connecting to ground.
Ground Connection:
To continuous metallic water system. When water system is not available, use ground rod.
Elsewhere, the power company says the water system ground is all NEC requires, but the company requires a service entrance ground rod also (they don`t say how long or deep it must go).

Capra`s No. 6 AWG stranded copper should be fine for grounding.

Best regards, Richard Harrison, KB5WZI

Not in my experience (the antennas change too often for that). If it
did, would it matter? If it matters, use that rope to hold a pulley.
>
>How do you tune the dipole after the ends are up in the tree?

With a tuner next to the rig.

>
>guess you just have to pull the whole thing down and start over.
>

Hi capra,

Now you're getting the idea of it.

I got my tree trimmers to install a lag eye-bolt high in the canopy
with a pulley attached and threaded with a continuous loop of 1/4th
inch black nylon braid rope. The other end of that loop passes
through another lag bolted pulley at the bottom of the tree. In other
words, just like a flag pole. Instead of raising a flag, I raise a
pulley holding another length of black nylon woven rope. This is the
rope I attach my antennas to, the other end (secured at a cleat - as
is the flagpole line) providing both tensioning and positioning. That
lag bolt is 10 inches long with 6-8 of those exposed. The limb would
have to grow remarkably to threaten overgrowing the fixed pulley!
This also presents less damage to the tree where rope abrasion could
lead to infection sites.

I had them do this to four Maple trees. This gives me XYZ control. I
can situate any design anywhere within the volume of space encompassed
by those fixed pulleys. This allows me to investigate a large variety
of designs.

I also have a long wire cast over the canopy for several hundred
feet. I got that woven through the branches with a slingshot. Been
there for years. It is tied down at the far end with 1/16th inch
white nylon braid. Over the course of those same years, there have
been accidents. The winds around here are not ferocious, but this
time of year they have the power to snap trees like mine in half. I
watched two of them snap in front of me. I am talking about 60 foot
tall Maple trees whose girth at the break point was easily 16 inches
some 30 feet above the forest floor. There is a 30 foot tree top

lying ridge-pole style between other trees, 30 feet up, beneath which this long wire wanders. Some day gravity will test the tensile strength of my system - again. I already had a several hundred pound limb fall across it.

This random wire is simple house wire, THHN #12 I believe. It is secured with 1/16th inch nylon twine at the far end. At the feed end it is secured to a lag bolt (actually one of those TV antenna standoffs with the ribbon wire adapter in the grommet) before going to an isolation box bolted to a 4x4 in a concrete pier. I secure both ends because the canopy has a lot of "spring" to it. Then this limb (about 20 foot long) came down on it. The 1/16th inch nylon twine wasn't fazed one bit, it stood. #12 house wire took the strain without a break, it stood - but apart. The 4x4 lag bolt stood - straight out. No hook in it anymore. It was the first point of failure. With that failure, the isolation box now took the strain and became the second point of failure as it was ripped off the 4x4.

Now the tension was evenly divided by the isolation box antenna connection and the drive line connection - both failed (simultaneously?). The box didn't go far because it was also tied down to ground radials. Perhaps the more successful connection not yielding to the tension. Any way, it took more effort to find the end of the wire (pinned under that huge branch) than to re-solder it to its old connection. I put a new bend back into the lag bolt. A new feed line replaced the old and I was on the air. Just like resetting a fuse. In other words, if I improved it any, it would force the failure in a less accessible area (I'd be in the woods).

I am continually amazed that I can get away with putting that common white nylon twine to so much work. My Army surplus field vertical kit for a 40 footer uses 1/8th inch nylon which would require a tank to rip out.

After 13 years as a computer consultant in California I moved to
Washington and at the same time decided to get into sales where the
big money is. I got a job as a Xerox copier salesman. I received 6
weeks of very high end training and was then a salesman in my own
territory working for the authorized Xerox agency in town. I am a very
honest person and never lied to clients when I was a consultant.
Well, I quit after 6 months and got a job as a computer analyst.

Here is what I learned from that experience about sales to the public.

1) most customers are for the most part foolish and want to get the
lowest price even if it means getting lied to and ripped off.

2) most salespeople, lie, cheat and do whatever they can to get a
sale.

3) most companies support the practices in #2

4) It is hard for an honest person to sell against a low life because
people hear what they want to hear and would rather get screwed later
and pay less up front.

After this experience I will almost never believe what a salesman
tells me for the rest of my life. Cars, electronics, real estate,
health clubs,you name it, the world is full of dishonest liars. I have
seen the truth, but for someone who has not been where I have been
recently the truth is hard to understand.

There's also Radar Electric in Seattle, or Active Electronics in
Bellevue, or Surplus Dimensions in Tacoma. For dirt cheap cables I go
to Vetco behind Fred Meyers in Redmond. They also have a lot of air
variables (or used to).

Ron, K3PIDE wrote:
"Does an electrically short antenna look inductive?"

An "electrically short" antenna would be a grounded vertical, too short to be a 1/4-wave, or an elevated dipole, too short to be a 1/2-wave.

These antennas require inductance added to them for resonance. This indicates an inductance deficit before inductance was added for resonance. If the antenna has an inductance deficit, it is capacitive.

Normally no, but it's possible for extra power to arc over a bad
connection and change the SWR. Or maybe if moisture was a problem
within an antenna as already mentioned. But normally, no, it doesn't
change, and the SWR reading taken at the lowest power is the most
accurate. If you show an SWR that increases fairly linear as you add
power, it's usually just meter error in the SWR meter. Most all cheapy
meters show a higher indication as you run more power. Thats fairly
normal. if the SWR jumps fast, or is erratic, then I'd be looking
around. MK

For cables, it's often cheaper to purchase, from a broadcast supplier, both cable and connectors in bulk. You can find premium connectors and print up your own interconnects for less than what comparable lengths of mediocre interconnects run at places like RS. You've also got the added flexibility of making single continuous runs, instead of adapted together cables of standard length, and inferiour quality.

For components, there's no question that RS is not the way to go. You can find better for much less at a real electronics store, when you can find them. Parts Express, and their equivalents are excellent choices.

Here of late, I've bought all my chip upgrades from Digi-key. With tax, title, license, old battery and recappable tires, I've spent about half of what I would have at brick and mortar retail for premium chips. And gotten what I need next day, when necessary. But by keeping a small inventory of commonly used items, I have what I need when I need it, and rarely have more than $20 tied up in warehoused parts. The added benefit is that I rarely have to pay premium rates for overnight shipping.

I have no cause to contradict the above, but if higher power results in higher analog meter readings, accuracy is usually a percentage of full scale. That`s a small error for large readings, but could be significant at small deflections.

This will work, but the efficiency will be low. You'll need the absolute best ground system you can manage to put in (a large number of radial wires) if you hope to get even modest efficiency. This kind of antenna has more wire loss than a straight wire antenna, and it'll take much more of a beating from ground losses because of its low radiation resistance. I've made lots of QSOs with a watt or so radiated power at 7 MHz and above, but you'll find it to be a challenge on 160. You'll probably be in the 1-10 watt range of radiated power if you apply 100 watts to the antenna. If you apply a lot of power, the heating from the wire loss might get great enough to melt the PVC. If it does, don't mistakenly blame it on the PVC, as one well known writer did some years ago.

Joey,

I assume your reference to "modern" glass means that they are tinted. I found out the hard way that some of the tinting has a lot of metal in it, which really screws up the SWR. I don't know if one can re-tune the antenna as I've never tried, but maybe someone else has.

Possibly a little off Subject: but here is what I have in my 'new
construction' (1999 code) house in rural Atlanta, GA area:

House copper water plumbing system is elecrically isolated from the
water meter by PVC pipe supply line.

Ground rod installed at the service entrance (meter).

The surprise (for me) is a wire connecting the house copper water
plumbing to the natural gas line under the house (crawl space)!!

Sorry, but "trickle down" is a fraud. Airtight proof below.

Ask any qualified economist what percentage of his economy is
driven by consumer spending. He or she will come up with
something around 2/3. Certainly the majority of it.

Then ask him what percentage of that 2/3 is contributed
by luxury item purchases vs. necessities that "ordinary"
folks in the middle and lower-middle class buy, and I'd
be willing to bet a dinner at Four Seasons the bulk of it
that our economy runs more on sales of economy cars
and bread than Mercedes, luxury cruises, and caviar.

Now take the vast numbers of consumers who are
middle class or below (and all of whom need to eat,
consume consumer products, etc.) and contrast that with
the perhaps 5% rich whose basic consumer needs are in practice
that much higher. The average "middle class car" is what, $20,000.
The average "rich person's car is not, on average, the 20 times
higher or $400,000 it would take for his contribution to even
reach half that of the 20 average folks he's above on the
economic ladder.)

P.S.: The 1960's provide solid proof of my assertion. They were
the greatest sustained period of economic growth in real terms
this century, AND one of the highest standards of living in
American history. One breadwinner could support a family, own his
own house, and work around 40 hours a week to do all this.
This hasn't been possible for most middle-class folks for over
20 years.

SO QED. "Trickle down" is a self-serving crock, that has
no basis in reality except that it makes a certain kind of
greedy rich person feel virtuous when no such feeling is
actually justified.

Source record: 154240

Baring the unusal as the arcking, the cheap and even some more expensive swr meers will be more accurate at a higher power level. The reason is the reverse reading diode will not get enough voltage to get out of the square law reagon like the forward diode is. That makes the meter read higher (and closer to the true swr) as the power is increased up to a point. This effect will usually disapear around 20 to 50 watts.

> Normally no, but it's possible for extra power to arc over a bad
> connection and change the SWR. Or maybe if moisture was a problem

2432. Will this 160m Vertical work?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-21 23:34:15 UTC
From: John Sicotte <jsicotte@earthlink.nospam.net>
Message-ID: <XRWK7.1137$oF.125803@newsread2.prod.itd.earthlink.net>
Source record: 154244

I am going to build a 1/4 wave 160 meter vertical antenna. I am going to use 30 feet of PVC pipe and wrap 133 feet of wire around it. It is going to be continuously-loaded. That is to say, the wire is evenly wrapped around the pipe with the coils about 3/4 inch apart. Of course I will have a good ground with ground radial wires.

Will this work? I have never seen plans for a continuously-loaded antenna before - am I missing something?

Thanks,
John N7MTB

I've been amazed at this whole thread. I never realized that you
couldn't be fired, or fire the job simply because either party thought
the other wasn't worth messing with. Sounds like 'modified welfare'.

It does work both ways, but don't look for a great reference from your (former)
employer if you exit in the middle of a key project!

--

I'm as irritated as the next person with lousy service, lazy attitudes, and
poorly-trained employees that seem rampant in retail. However the saying,
"you get (no more than and probably less than) what you pay for" applies to
employees too. If you pay less than a living wage (which varies from area to area a
lot), you're going to get people who are too dumb, lazy, or otherwise unfit to get
a "real" job. The ones with reasonable ability, drive, or skill aren't going to
settle for a minimum-wage job except maybe as a supplemental income for school or
for flexible time reasons.

Thus, as the cost-cutting trends continue, it's not just the quality of the
merchandise that suffers....

Will consumers eventually start voting with their dollars in favor of some quality
service alternatives, or will the bottom line eventually cause us
all to shop in automated warehouses full of vending machines, as another poster
noted?

I have the FT100 with the ATAS and yesterday, while mobile in Albany
NY area, there was a band opening on 6 meters. I worked Baja CA,
Arizona, and Ireland while in motion. Signal reports were anywhere
from 5-5 to 5-9 on my rig.

Now this was one helluva band opening to be sure, but I was quite
pleased with the reported performance from my contacts, and the
percieved performance from my ears.

I am quite pleased with this combo. I worked England and Germany today
on my way home to NH on 17m.

Mine works...you often have to add a small counter poise. I took a little marker flag, eyeballed about 14 inches (arbitrary) snipped the wire mast, bent a loop in one end and with a washer, squeezed it on the interior connector where the coax connects.

It dropped SWR from 2.3:1 down to 1.3:1 on the first try...no science, just snip, bend, screw...all done. Some scientist in here might beable to optimize that a bit.

Richard,
I always thought braid (from old coax) should work very
well for grounding. But after fighting an intermittent
ground problem on a mobile for years I finally solved it by
getting rid of all the braid ground straps. The smog and
other corrosive 'stuff' in the air gradually deteriorated the
braid till it would become intermittent at connections. After
a winter with salty roads, it would sometimes crumble to a
pile of copper 'stuff'. Had the same thing happen to braid used
for grounding in the shack too. You may be lucky to live in
a place where you don't have much smog (or whatever you want to
call it) and get by with using braid for grounding. Unfortunately
here in Oklahoma, we have too much 'stuff' in the air (who'da
thunk it?).
The 'tinning' I was referring to was with rosin-core solder,
the kind I had handy. It makes the braid last longer, but it's
not too cost effective.
'Doc

Yes, but you're not an average consumer. If you actually insist on
seeing the return/repair policy in writing before you pay for it,
you're really not an average consumer.

Well, back in the stone age, you could be fired for any reason. With
the rise of union power came the 40 hour week and all sorts of other
niceties, among them that you had to have cause to be fired, and, I
believe, you had to be put on some sort of probationary period so you
could see it coming. At will employment removes those restrictions
on the employer, but also removes the restrictions on the employee to
give two weeks' notice.

Source record: 154261

Hi John, yes it will work quite well if done correctly and efficiency will be better than 30 % but the biggest penalty will be bandwidth (less than 50 kHz) so set the center frequency where you want to operate. First paint the PVC pipe so it doesn't break down, then get 270 ft (when building a short antenna double the length of wire and cut from there) of #10 wire. Buy or borrow an antenna analyzer (or you are in for a tough job). Wrap the wire tightly around the PVC mast and tape off, connect one end of your wire to the ground and radial system. Use as many wires as you can, the number of radials are more important than length but try to use 70 ft or more this is one of the keys to high efficiency . Fabricate 2 conductive rods 8 feet or better (as long as possible but keep in mind wind loading) and solder on alligator clips halfway minus the diameter of your mast , one on each rod. Now install (drill holes in mast) the 2 rods at the top of the mast in an X shape (capacitance hat). Next unwind the wire letting it separate from the mast by an half inch or so (it can move back and forth freely from the mast) and clip the top of the wire into the alligator clips on the cap hat. This separation from the mast is important to reduce losses. Connect the shield side of your coax to the ground (radials and bottom of the coiled wire), solder an alligator clip to the center conductor (strip to 8 " or better). Clip on to the wire coil about 6 windings up or so, now connect the analyzer and start trimming the top of the wire till you come close to your operating frequency (reclipping to the cap hat after each cut). Stay well below your frequency for now and start experimenting with moving the clip on the coax to lower your SWR. Go back and forth between cutting and moving the coax clip until you find the best match and frequency. Either leave the clips on, or for best efficiency solder permanently in place.
Now you have a high efficiency DC grounded short vertical with inductive matching.
How do I know it works? I use a 5 foot 30 meter vertical that I run QRP, and I get very good reports (very good ground here).

Good luck and have fun!
Cliff

True, but in that sort of cast it usually won't happen,
anyway. Besides, negative references can bring on
lawsuits, so aren't given that often. Some of my
past employers won't give references, only confirmation
of employment, because they're lawsuit-gunshy.

2451. SWR & Antenna Efficiency

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-22 04:26:10 UTC
From: new general <jerryaa@prodigy.net>
Message-ID: <C7%K7.1426$ow.130148568@newssvr16.news.prodigy.com>
Source record: 154265

I may be oversimplifying Maxwell in Reflections II.Loosely paraphrasing He states there is an obsession with SWR by amateurs. That with the exception of modern transceivers unable to accept loads with SWR of 2:1, that we are entirely too obsessed with SWR, that antenna efficiency is more important.

I did an analysis on Reg Edward's dipole 1 program. Using 7.116 mhz. 50 ft rg8x line 35 foot off ground. Dipole length 65 ' 9" He apparently uses 474/f mhz instead of the standard 468/ f mhz. Got an efficiency of 73.8% with 1:05:1 SWR.

Changed to 450 ohm center fed same dimensions and got an efficiency of 86.7% with SWR of 12.2:1.

Now the problem is the rig won t accept that SWR without an antenna tuner. If antenna tuner is added, how does that addition affect efficiency? Is the changing of the feedline to 450 ohm flat line worth the added efficiency ?Do you think Reg's evaluation via his program is valid in re: efficiency?

It's not clear to me whether the 12.2:1 is the 450 ohm SWR or the 50 ohm SWR. Assuming it is the 50 ohm SWR, you can correct the problem by making your 450 ohm ladder-line 1/2WL long. For 7.116 MHz and a VF of 0.9, that would be 62 ft. So change your 50 foot length to 62 ft and you won't even need an antenna tuner as your 50 ohm SWR will be back close to the original 1.05:1. With no tuner required, your question becomes moot and the dry ladder-line will give you better efficiency than the coax. Note I said "dry". Ladder-line is lossier when it is wet.

Jim wrote:
"House copper water plumbing system is electrically isolated from the water meter by PVC pipe supply line."

PVC is common. NEC requires a metallic cold water pipe system inside the house be connected to the electrical service ground (usually a rod as in your case) to eliminate the shock hazard between a water piping system in the house and the electrical ground system which now includes every device connected to the electrical system (well, there are some double-insulated devices that aren`t grounded).

Jim also wrote:
"The surprise (for me) is a wire connecting the house copper water plumbing to the natural gas line under the house (crawl space)."

Yes, the problem with grounding the gas line is shorting the cathodic protection potential the gas company applies to the line and overloading the "rectifier" the company uses to supply the d-c current to the distribution line, if too many customers are doing likewise.

The d-c cathodic protection potential is applied to the pipe to induce ions to flow toward the pipe instead of away from the pipe. Migration in the reverse direction would erode the pipe away.

Rectifiers are placed at strategic points throughout gas transmission and distribution systems for corrosion control. Rectifier output is applied between the pipe and a ground bed some distance away.

To keep the quantity of current reasonable, gas pipe is coated with paper, tar, pvc, etc. by continuous coat, spiral wrap tape, or whatever works. The gas company either directly or through your house builder probably had an insulating flange installed at your gas meter. You can probably see pipe dope or tape on the supply side pipe and see no insulation on the outlet side of the meter. The outlet could be insulated too if the builder were really dedicated to minimizing problems you might have in 40 or 50 years (Naaah!) Between the pipes you can probably read the small d-c cathodc protection potential on the gas company`s line.

The gas company dug a big hole in my next-door neighbor`s front yard today. The neighbor probably had a ground, inadvertently, which indirectly rotted out the gas line serving the meter. I hope there was enough electrical resistance in the neighbor`s pipe so that some potential from the gas main remained on my pipe to prevent it rotting away too. It may only be a short time until grass is dead in my yard and people are smelling mercaptans. I hope not.

Wow! I wonder if I can remodel it for the HF bands?
P.T. Barnum said it all! The horrible thing about it is
that they will likely sell lots of them to the
unsuspecting. Maybe I could crumple up my dipole and put it
in a can -- or would that be too close to a fractal antenna?

Doc wrote:
"The smog and other corrosive "stuff" in the air gradually deteriated
the braid `til it would become intermittent at connections."

True that surface contacts may not be very good if the copper making
those contacts is corroded. In coax shield, the corroded wires in a
braid shield will likely increase the coax loss.

I`ve experienced black waveguide surfaces in Port Sulphur, Louisiana and
was hardly able to measure any degradation in microwave performance.
I`ve experienced plenty of green copper surfaces in all manner of
electrical and electronic equipment with no noticeable performance
degradation.

I worked in KPRC and KXYZ in Deepwater, Texas in 1949. The stations
shared an antenna system. The same radials are serving KXYZ at this very
moment and are certified to the FCC to be up to full performance. Lots
of stations built in the 1920`s are still doing very well with the same
copper radials buried in swampy ground or desert sand.

This copper deterioration stuff is largely a myth.

In my occupation (machinist) it is standard practice not to give notice. If you are starting a new job on Monday, you tell your present employer on Friday. It does work both ways though. Layoffs are fairly common. You are generally told at the end of your last day. Sometimes you show up to work and are told to go home.

Source record: 154268

Nothing you put at the rig end of the feedline (where antenna tuners usually go) will affect the efficiency of the antenna or feedline. (The efficiency is the fraction of the applied power which is radiated as opposed to being turned locally into heat.) What the tuner will do is permit your rig to deliver more power to the feedline. No antenna tuner is 100% efficient, either, and depending on the tuner design and adjustment, and the load it sees, a considerable amount of power is sometimes lost in the tuner. So a tuner will always further reduce the fraction of applied power which is radiated. Again, though, if your rig won't deliver full power without a tuner, the tuner is still likely to increase the total amount of power radiated, by allowing the rig to apply more power to the system.

Let's take an example. Suppose your antenna/feedline is 90% efficient and your tuner is 90% efficient when presented with the impedance seen at the input of your feedline. You have a nominal 100 watt output rig, but it's shutting down to 25 watts output because of the impedance it's seeing. Without a tuner, you'll be radiating 0.9 X 25 = 22.5 watts. With the tuner, your rig's output increases to 100 watts. So you'll have 0.9 X 100 = 90 watts coming out of the tuner. The antenna/feedline efficiency is still 90%, so you'll radiate 0.9 X 90 = 81 watts. This is an improvement of just under 6 dB, or about the gain you'd get by upgrading from a dipole to a two or three element beam.

Suppose, though, your rig did deliver its full 100 watts to whatever impedance you see at the input of the feedline. Then you'd be radiating 90 watts. Adding the tuner to reduce the SWR seen by the rig would do nothing but convert 10 of the rig's 100 watts into heat, leaving 90 for the antenna, 81 of which would be radiated. (This half dB loss isn't significant, but you get the point -- the tuner didn't help -- and the tuner loss could be greater than the example.)

The only importance of the impedance at the input of the feedline (commonly described as SWR even if it's not actually the SWR on the feedline) is that if it's too high, your rig will reduce its power output.

This "mini" screwdriver works quite well. Most owners will tell you that 17m is its best band, surprising though 10m is only OK (an Wilson 1000 does better). I thought 40m might be a dummy load but I get reports of 5-7 there very often. Mine runs all bands 10 - 40 with no problem. This antenna performs as least as well as your 17m hamstick (I have one too) because even though it is shorter, the 1.25" or so base greatly increases the efficiency where the current is greatest (countering this a bit though is the small wire used on the loading coil). Also important is that you can mount it up on top in the clear (even on my full size 4x4) instead of being mounted on the corner of the vehicle when pattern is effected and capacitive losses to the metal (side of vehicle- bumper mounted) reduce efficiency. Don't get me wrong the ATAS 100 does not perform as well as a full size screwdriver (which is a lot better than a hamstick except on 10 or 12m) but there again there is that XYL factor...

I just downloaded the Eicar test files and got an interesting result. I am running Win 98, and use Surfin Pro, ANTS, and AVG.

My Surfin Pro instantly detected the Eicar files as they were about to download. Neither ANTS or AVG alarmed.

When I had AVG scan the Program Files folder (which has the downloaded Eicar files, AVG did find them and ID as viruses.

The question I have is whether my anti-virus should have alarmed at the beginning of the Eicar files downloads?

==========
John,

The sort of antenna you describe is often called a "Helical". It is a great height-saver. In the UK it is often used for Top Band mobile. It allows the vehicle to negotiate road bridges.

You have a height of 30 feet available for 160m. This is not a particularly short antenna for that band.

The helical winding is just a streched-out loading coil. The reason for stretching it out is that it allows very thick wire to be used which will have a low loss resistance. There is no point in having 30 feet of helix if thin wire is to be used. When a height of 30 feet is available a helical winding of 3/8 inches diameter copper pipe is appropropriate. Otherwise a large bottom-loading coil wound with close-spaced 10 or 12 AWG enamelled copper wire would be better and much more convenient to construct.

The good ground system you propose is absolutely essential. Most of the loss in very short vertical antennas is in the ground connection. There is not much point in using a helical winding of copper pipe, or a great fat loading coil, until the ground connection loss resistance has been reduced to less than 4 or 5 ohms.

You mention a helical wire length of 133 feet. This, as you know, is a 1/4-wave on 160m. It is a popular misconception that an antenna can be shortened by cramming the same length of wire into a smaller space. With very short antennas, for 1/4-wave resonance, the length of wire in the helix is crudely in the order of 1/2-wavelength. Much depends on the diameter of the plastic coil

former. There is no usable relationship between resonant frequency and length of wire in the helix.

But don't let me put you off experimenting with helicals. As I have said above, their advantages apply to heights very much less than 1/4-wavelength. For 160m first try something like a 2" plastic pipe length of 8 or 12 feet, top loaded with a 4 or 6 feet whip.

Use a lot of shallow-buried radials. But radials need be no longer than overall height of antenna.

To find the number of turns of what gauge wire on which diameter pipe for resonance on what frequency download program HELICAL3 in a few seconds from website below. Several other modelling programs are available for short, coil-loaded antennas.

Brian Kelly wrote:
> What you said was that a 414 foot long wire WILL fire off it's end.
> Period.

And it will, Brian. Even an off-center fed resonant dipole
fires more RF toward the long end. An end-fed long wire is
just about as off-center fed as it can possibly be.

> How did "most hams" and/or anything about coax get into this
> discourse??

Where have you been? It came from the question that was asked in
the original posting. Here's the quote from that original posting:

"This weekend I put a 414 foot long wire SE to NW direction up
40 tp 50 feet. I did feed with a 450 ohm ladder line all the way
to the MFJ Tuner."

> We all know that feedlines aren't supposed to radiate but you see
> Cecil end-fed wires don't happen to have feedlines Cecil.

Please read the original posting. He said he fed it with 450 ohm
ladder-line. Last time I checked, 450 ohm ladder-line fulfilled
the definition of "feedline". Look up "End-Fed Zepps" in your
antenna book, Brian, to see how most hams feed their end-fed wires.

I'm assuming a full scale forward reading in both cases. "set postion"
on most cheapy maters. I've seen many that will show a good bit higher
readings when using higher power. Say if you ran 1 watt, and read 1:2
to 1. Run 100w, and reset the meter, and it might read 1:4 to 1. I
consider the 1:2 to 1 reading the most accurate as the change is just
meter error. MK

Art,
I haven't seen/used one so all of this is opinion.
My opinion is that I have to be very skeptical of the
GAP Super"C" antenna. In GAP's explanation of how the
antenna works, and we all know about manufacturer's
advertisements, they start out with a false assumption,
then go on to prove the assumption is false. I just
can't 'see' this as proving that the antenna works. It
puts me in mind of a 'scam' on GAP's part.
The GAP Super"C" also puts me in mind of the
"Isotron" antenna. If 'GAP' is trying to 'one up' on
the 'Isotron', I think they missed the boat.
I think I'll wait to hear a few user comments about
the GAP Super"C" before rushing out and buying one...
'Doc

How high is it, and how is the feedline routed in? I was thinking you
might be able to feed it as a T antenna against a good ground using a tuner.

Wrong, he didn't get what he paid for. He paid to get a WORKING rig the next day. He did not get it. He got a broken rig. Why should he have to pay AGAIN for overnight shipping. Plus, how often do you here the excuse, "It's not our fault, its the manufacture's fault." They are the ones I you paid your money to.
Bottom line, Texas Towers did not live up to their agreement. From the original post I also gather he had to pay return shipping for an out of the box defective product! What a rip off.

Consumers should always verify the following:
1. The actual return policy.
2. Verify with UPS, FedEx, etc what the ACTUAL shipping charge would be. This is where a lot of mail order places really make their money, over charging shipping.

This is not just a Texas Tower problem. It is nation wide. Buisnesses now think that they are donig YOU the favor just to take your money.

Speaking of transmission buisness. Why is my price ,off the street, for a transmission DOUBLE what is charged to other parts houses, garages, etc? Mine went out and the cheapest I could find was $2850. My nephew was the manager of an Auto Zone, He called tha same place and bought it for me at his price, $1400. No wonder there is such a market for chopped/stolen auto parts. The real theives are behind the parts counter.

If you are going to use 30 foot PVC, then you will probably use some sort of guy wire. Depending on how far from the base you are going to guy, make the top portion of the guy wire with #10 copper, then the rest with a non conductive rope or poly, using an egg insulator, then use the guy wires as a capacity hat as mentioned in an earlier post. Top loading is more efficient, so I would wind a helical to the last foot, then mount a large (10 inch or so diameter) coil at the top. This will require some tuning so be prepared to raise and lower until you get it right, then solder and seal everything.

Why should the customer have to pay extra after receiving a defective
product? Your post really makes no since. You imply that the customer is
in the wrong.
As long as this type of thinking prevails, suppliers will not even try
to clean up their act.

A number of years ago I ordered a printer and it arrived DOA. I called
the supplier. Not only did they immeadiatly ship a new one, but they
also arranged UPS pickup and return shipping. Not one more cent out of
my pocket.

Bottom line is Texas Towers, by accepting his money/order, agreed to
deliver a working product the next day. They didn't. Why should the
customer have to spend MORE money to cover THEIR mistakes????

Dave,
It really won't matter too much, using an antenna
at half it's fundamental frequency doesn't work too
well. Using a tuner may help, depending on the 'range'
of the tuner.
As far as a 'choke', for 80 or 40 meters, something
around 4-8 turns should work...
'Doc

It always amazes me, someone should do a study on Radio Shack. I complain just as much as the next person, but everytime I go in to buy a PL259 (BTW they have silver now, but no ceramic) connector there are people there buying scanners, TV's DVD's and yes cell phones, lots of them. I have never seen a RS go out of business. Some of them do actually have knowledgeable people, but not a lot. It seems everyoine hates going in, myself included, but I probably spend a considerable amount a year there, it is just convienant and easy. I admit I own RS HT's, the new and old, RS shortwave receivers, DX300 and some portables, RS Mobile 2m's, a scanner and assorted other items, almost all purchased as closeout or good sale. BTW, I was able to get a schematic and service manual from them for my DX300, and they replaced my HTX202 when I fell in the bay and wetted it. With all their pain, they seem successful, with the exception of incredible universe fiasco.

I guess part of it is my priorities change, time is now more valuable, so quick is better and worth the pain.

I think you are asking a bit much to ask them to pay for overnight shipping
because Icom built a defective rig. Have a little patience.

Jeff,

He paid TT for the rig. He paid the express shipping company to get it
there overnight.

Three weeks ago, I e-mailed both Texas Towers and AES and asked what
they wanted for an Outbacker Perth, a Tri magnet mount and shipping. I
received an automated reply from AES immediately confirming my message and
saying they would reply within 3 working days. 48 hours later I had a reply
from AES, I sent them a money order for the gear and less than one week
later was using the Outbacker (great antenna!!). Guess what? I still haven't
received a reply from Texas Towers! I think they need to work on customer
service.

2492. Grounding a disclone?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-22 18:25:58 UTC
From: Steven Dunton <steve@nevetasNOSPAM.com>
Message-ID: <9tjfvp$6i7$1@news8.svr.pol.co.uk>
Source record: 154197

I've just acquired a 2nd hand Sirico disclone aerial. I'm going to put it on a 16ft pole to the side of my house.

However do I need to ground the aerial in some way? If so how?

Cheers

Steve

2493. 40 meter Dipole for use on 80 meter

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-22 18:43:42 UTC
From: pasitrepnospam@pa-sitrep.com
Message-ID: <3bfd45df.83782137@news.city-net.com>
Source record: 154182

I'm putting up a dipole for use on 80 meter, specific frequencies to be used will be 3.983 thru 3.9935.

What length or frequency should I tune the 40 meter dipole on to be able to best tune the antenna for the 80 meter frequencies I'm shooting for?

Also, if anyone out there has an ARRL handbook, could you please check and tell me the diameter and number of winds I should use for my coax choke balun for my specific application. I'll be feeding the antenna with 50 ohm coax.

Thanks in advance for any help.

You could have been a prick. And you should have told the manager
that.

You could have called them up, ordered ANOTHER rig and paid for
overnight.

Then you could have taken the first rig back to UPS, and shipped it
ground to them with an RMA and refused the first rig on your credit
card as received defective.

I've dealt with people who just don't get it, and pull 'technicalities' on
customers like this.

Then I've also dealt with companies that if it isn't right, have a
replacement
ON THE WAY immediately, at their expense.

I had an order from Everything Wireless in Florida go bad last fall when
I tried to get a GPS. Know what? Once they realized it, THEY offered
next day air, AND threw in a car kit for free.

I had UPS loose a weather station I ordered from TAPR. Know what
happened? TAPR as soon as they realized it dropped another one
to me immediately, with an email that if the first one shows up to please
send it back...

Now, you can deal with people who treat you right, or you can deal
with people who SAY they give you a deal, but then fall back and whine
if something goes wrong. Sometimes that little bit extra you pay IS
worth it. And a lot of times, you don't even have to pay that little bit
extra.

Thing is, I've heard stories about Texas Towers before, from way back
in the 1980's when I first got my ticket when I lived in Ft Worth.

Some things never change.

If you're REALLY such a good friend, why don't you print out the
original posting, take it to him, and say "HEY!! You F***ED UP on
customer service! What are you going to do about it?"

Now, his reaction may be he takes the letter, looks into it, and at
LEAST someone gets a letter of apology.

Care to do it and post here what happens?

Sorry Dennis, but if someone doesn't want to run a business that's
responsible
to the customer, fine. But if someone takes my money for a service or a
product, I think I'm fairly justified in expecting that I GET that service
or
product.

Or is that something unreasonable?

Unfortunately, it seems that to some dealers it is. They don't want to
sell. They don't want to offer service. They just want to sit on their
lazy ass and be clerks that take money as you walk out the door.

Mike

I've had nothing but great experiences with Texas Towers with the exception of one case where they shipped me a microphone with the wrong connector. They do have the best prices and I'd hate to see them go out of business. You should understand that the ham radio market isn't that lucrative in the first place. The fact that they're willing to return the radio to the manufacturer for you seems to me to be very generous on their part. The defect was the manufacturer's fault, not theirs. If they wanted to, they could have just told to to deal with the manufacturer yourself. Technically, once you open the box, you own the radio and any problems it may have.

: >more than $33 on the sale. He had you pegged as a buyer shopping for
: >price ... only. You'd pass him up for a $10 less price in a
: >heartbeat. He knew that, and acted accordingly.
:
: So are you saying this dealer advertises the lowest price, takes
: an order at that price, than pegs his customers as a bunch of
: lowlifes looking for nothing but the lowest price when they have
: problems with what he sent them and ask for a bit of customer
: service? Sounds like a self-fulfilling prophesy.
:
It sounds like everyone was asking for trouble on this one. A Comm
company (2-way sales-service-installations) I used to work for fully
supported amateur radio because there were several hams working there,
but we would always have to put on our hard hats and fire suits. We
were always expected to give custom service for below the advertised
basic rate, even though custom work could cost us several times more
than the bread and butter commercial install. Issues like custom
placement and mounts, routing of wiring and cabling, additional
equipment and multiple radios and interference issues could take a 30
minute job into hours or even weeks if special orders were required.

Remember that Murphy, and the inevitable diabolical perversity of
inanimate objects will always plague us. Truly TT could have handled
this better, but someone shopping for price should always consider
staying within the margins of an invariably limited system that allows
for a tighter margin.

Remember the I Love Lucy episode with Lucy on the assembly line?

I have a McDonald's story that illustrates this concept too. I wanted
extra catsup on my Big Mac at the drive through window, and they
instantly shifted into special customer mode. They pointed me to a

waiting area to park my custom car and advised me that someone would assist me momentarily. Fifteen minutes later someone walked out to serve me my Big Mac with extra catsup on a tray. I didn't have the heart to tell them all I wanted was a couple extra packets!

Thanks for the reply, Doc.

I would love to make a dipole resonant to 80 meter but that just isn't
in the cards.

I think what I'm going to do is tune the antenna for 7.272, which is
an emergency comm secondary freq used in PA, and use the tuner to get
it going on 80.

I have a Marconi that tunes well to 80 that is working okay, but I
want to try better the performance with a dipole.

Just for laughs, how would you "ground" it at VHF?
DC isn't a problem, but 20' up on a mast, you're several wavelengths from ground, depending on freq.

>shooting for?

Hello,

I'm not sure whether you intend to put up an 80 meter dipole (about 115 feet long) or a 40 meter dipole (about 65 feet long).

A coax-fed 40 meter dipole (about 65 feet long) will not work very well on 80 meters. The feedpoint impedance of such an antenna will be a few ohms resistance in series with a lot of reactance. End result is a very high SWR on the coax and high losses in the coax if it is more than a few feet long.
>
>Also, if anyone out there has an ARRL handbook, could you please check
>and tell me the diameter and number of winds I should use for my coax
>choke balun for my specific application. I'll be feeding the antenna
>with 50 ohm coax.

In my opinion, a W2DU bead balun is a better choice.

I think you're flat out wrong with that statement. Here in mass there's a
warrantee of what I think is called 'implied merchantability' or something.
Anyway, places can put up all the signs they want, but if it's unusable
at the time of delivery, unless it was sold 'as-is', they HAVE to take
it back.

As to mail order with a credit card, all a user has to say is it was
defective
on delivery. It just don't matter, again unless it was 'as-is' up front.

Texas Towers is selling merchandise that is implied to be new in the box
and usable upon receipt. Hey, it's not their fault if someone gets
something
bad from a manufacturer.

But it SURE AS HELL IS THEIR RESPONSIBILITY.

Should the customer take care of the problem? Why should he? HE
didn't make a profit on selling the item, the SELLER did. If the seller
claims he won't make money, as one person alluded, I'd have to ask,
is he THAT STUPID to be in the business? Come on here. Your
attitude that it's the buyers responsibility is BULL DROPPINGS!

If YOU are in a retail business with this attitude I sure as hell don't
want to do ANY kind of business with your store!.

Doc,
Thank you for your comments. Yes I have read the explanation. I have a rule not to judge things unless I have used them, and the explanation makes it out to be a champion DX, which is a pretty big claim considering the antenna is a mesh box 3 feet tall. It a big order to fill, so we will have to wait and see. Art - NH7FL

Hello,
I live in a very densely populated area of Kent UK.
Unfortunately I am currently living in a first floor flat with buildings rising to three storeys all around me. A long wire is impractical so I am looking for a reasonably priced H.F. antenna to mount on the roof. Perhaps an active loop or vertical of some kind. My receiver is a Yupiteru MVT7100EU, and I listen below 30Mhz mostly. I also listen to local output above this but this is not my main area of interest. The USAF H.F. network, primary on 11.175Mhz and numbers stations. Also commercial airlines world-wide. I realise that for VHF/UHF I will need another antenna, plus a quadrfilar helix for satellite imaging at a later date. But it is the H.F. bands I am missing at the moment. Any help would be gratefully received....

Les

>Mike

I'm about 200 miles from the place, will be in there sometime in the
next two months! However the post was not to expand on what and if and
so on, only to show how difficult it is make things work - all the time.

However, for either of us to take the time to hash it all out between
us, is going to be yet another X bucks worth of time for both of us,
which, might get an answer posted here in a couple of months..

I doubt that would really be useful.

I understand both sides of the issue.

In one business in which I'm a principal, but a non-control one, the
controlling principal's desk has a collection of bad checks in it
totally over $125,000 US in the stack. These were all accumulated over
some 20 years or so, and include instruments from probably 20 different
states. And that has nothing to do with the myriad of paper schemes
and whatever which go back and forth to get someone a 'better deal',
when it really ought not to be.

From experience, it has taken us probably $2,000,000 just to cover that
loss above. And the pile includes everything from just plain checks, to
Cashier's Checks, and even to bank paper which blew up when the bank
folded between the time we took it and the thing hit!

If I were to take it to Gerald, I'd likely find that there is a
personality difference between the people which is the focal point. Our
research at the same origanization above indicates that over 75% of all
these sort of things are really driven by personality clashes one way or
another. Even if I got an answer for you, it would be difficult to
convey all the meaning and the emotions.

In order to share a value judgment, each party must have some experience in common to do so. That's often very hard to do in cases like this. I posted my reply to try to create that common link, no more; no less.

--> Sleep well; OS2's still awake! ;)

Les,
The first thing that comes to mind is a simple wire
run up the side of your building to the roof. You didn't
say, but if your living in a 3 story building, that would
be something on the order of 36 feet of vertical antenna.
Not really 'resonant' on any of the frequencies you mentioned,
but who knows, may work just fine...

Dave,
Okay, but I'd make it a full wave length, or a multiple
of a full wave length for lightning, that's what I'd be
worried about providing a ground for. What's the frequency
of lightning in your area? Around my house, it's about 8 to
20 strikes per month...

If it is space you are challenged by, you might consider winding a couple of loading coils to shorten
the 80 meter dipole. Not as efficient as the full length, but it just might be better than trying to make
an antenna that is too short to begin with.

I would agree that Texas Towers has the best prices, but who wants to wait a week or two for a back order. I called about a Yaesu FT-1000MP Mk V ($2498 plus $25 shipping) great deal From Texas Towers. ($2549 shipped) from AES. I got it 2 days later from AES. I paid $24 more, but I didn't have to wait.

You should provide a ground for the antenna for lightning protection. RF performance will not affected by adding a ground, however.

Dave

If you only have room for a 40 meter antenna try the shorty all bander from www.spiromfg.com I think Van Gordon and W9INN have similar models. It is 70 feet long, fed with ladder line and will work 80-10. You'll need a tuner but it will work.

Reg Edwards wrote:
"I have missed the previous contributions to this thread.

On what transmission line does the enquirer wish to measure the SWR?"

That was not defined.

The original question from Jerry (new general) was:
"Is there a way to measure SWR, impedance, etc without going on the air?"

My responses demonstrated that I knew of no way to directly measure as proposed without using some quantity of r-f. It is r-f SWR, r-f impedance, and r-f etc that Jerry would measure. However, I consider the small amount of r-f used with admittance and impedance bridges not really "going on the air". Using a "Thruline Wattmeter" is "going on the air".

Some contributors are likely to consider the emission of any r-f, no matter how small, "Going on the air". That`s what makes a debate.

So I guess everyone who buys for him is pegged as a buyer shopping for price....amazing! Do you think that is why he offers a lower price? To get customers to purchase from him maybe? Isn't that something called competition? When a defective product is delivered, the supplier should make it right at no further expense to the customer, profit or no profit.

2530. Re: Will this 160m Vertical work?

From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <9tkgv5$i8v$1@neptunium.btinternet.com>
Source record: 154135

I had a private enquiry. Extracts from my reply may be of interest.
==========

I may have used the desription "capacitance hat" for a vertical rod or whip a little loosely. But tis a fact that anything attached to a vertical which is not a long wire has capacitance to the rest of the universe.

A vertical whip is the most simple method of top-capacitance loading an antenna. It has the added advantage of increasing the all important effective antenna height. A horizontal set of radials, or just one horizontal wire, will increase capacitance and allow a smaller inductance coil but does not increase height.

So if the loading coil, perhaps a helical winding, has enough inductance without reaching the top of the antenna then, because overall height is all important, by all means extend the antenna as high as you can go with a single vertical conductor of some sort.

A multi-radial wire capacitance hat is needed only on extremely short antennas. In that case the big capacitance loading necessitates a smaller inductance to tune it. The fewer turns needed for less inductance allows a helical close-wound winding to be wound with thicker wire. Thicker wire means a smaller loss resistance. It may not need a full helical winding at all - a bottom loading coil may be sufficient.

For mobile working a big top-hat disk or set of long radials is not possible if only because of wind resistance. So all one can do is go upwards as high as road bridges allow.

There is a danger when taking a helical winding straight to the top without any extra capacitance. Extremely high voltages occur at the top and ionisation losses will occur on high power. You have a Tesla coil. It may even catch fire.

When a height of 30 feet is available for 160 meters a relatively small bottom loading coil is all that's necessary. A long helix of thin wire will be more lossy. There may be some small advantage by having a loading coil at a height of 20 feet, close wound on 2 feet of 3" diameter plastic pipe. See program LOADCOIL.

A big disadvantage of a loading coil above ground level is that it becomes a one-band antenna. Without a loading coil along its length a 30 feet vertical, with a tuner at the bottom, is good from 160m to the 15m band.

A tuner or some sort of matching arrangement at the bottom will still be needed for the full 30-feet helical.

But don't let me put you off. HF Helicals are fascinating things to make, experiment with, and get around on. Transatlantic posssible from a 400-watt mobile helical on 80m if you try hard. 100 miles mobile-to-mobile with 100 watts on 160m groundwave in daylight.

Regards, Reg, G4FGQ

2531. Building a TV Arial

I recently bought a TV tuner card for my computer.

Unfortunately I do not have a connection to the main antenna on the roof going to my computer room.

I was thinking that I could make an antenna to receive the television transmission. Is there a way I can do this so that the arial size is relatively small, e.g. transportable for lan's and such?

Also there is a FM tuner inbuilt to the card. What would I need to receive the radio signal? Could i just use the television arial for the reception, e.g. create two leads from the arial.

Sorry for my crude description or knowledge on this subject but I am very much a novice, perhaps more than, when it comes to this area of technology.

I am anxious to build this so I hope someone in this newsgroup can help me.

Thankyou!

Actually, I believe the government also takes far more as a percentage of
the GDP than it did back in the 60s. I seem to recall running the numbers
a year or two ago and coming to the conclusion that if we simply took Jimmy
Carter's last budget, and adjusted it for population growth and the rate of
inflation, the government would be spending something like $400B *less*
than even the allegedly conservative (on spending) Republicans want.

I'd like to see somebody ask a politician what it is that consistently
makes the per-capita cost of government increase faster than the rate of
inflation when this happens in virtually no other sector of the economy.

Les wrote:
"It is the H.F. bands I am missing at the moment."

My experience with this problem dates from 1937. The new all-band radio set came with a dipole kit which we installed just above the roof ridge. The kit also included weather-proof wide-band transformers to transform the supposed relatively high impedance at each end of the transmission line to the 75 to 100-ohm impedance of the twisted-pair used as a transmission line. One transformer connected the line with the aerial. The other transformer connected the line with the set.

It all worked very well. The balanced system eliminated some of the noise a wire connected to the aerial terminal would pick up. The low aerial had little directivity so we could pick up signals from all azimuths and in spite of high vertical angle sensitivity we heard stations from all the world.

Today ferrites and coax are available. Put up a dipole, connect it to your coax with a ferrite balun, and connect the coax to your receiver. There will be impedance mismatch and a lot of loss on many frequencies, but you have a lot of excess gain in the receiver and automatic gain control will do a lot to even out the variations.
Enjoy!

Best wishes, Richard Harrison, KB5WZI

On item #2, realize the costs of shipping are more than just what UPS, etc. charge. Packing materials, labor, paperwork, etc., are also shipping costs.

I agree some places do get carried away with shipping/handling charges, but don't ask them to ship just for the UPS/FedEx fee.

That depends on whether it's VHF or UHF channels, vhf somewhat large, uhf somewhat small.>Also there is a FM tuner inbuilt to the card. What would I need to
>receive the radio signal? Could i just use the television arial for
>the reception, e.g. create two leads from the arial.

VHF TV antennas work well on FM radio freqs. Anything will work somewhat. To recieve both tv and radio sigs. from the same antenna use one feed with a throwover switch to go between tv and radio.

Lightning's DC, kind of hard to calculate a wavelength.

> 'Doc

Nowhere near that here. We get it through the spring and summer, but it's pretty rare the rest of the year.
Even our repeaters, on the tallest building in the county, have only been hit once in 20 years.
The 440 machine took the main hit, when I dismounted it, I could hear the shattered parts rolling around in the box.

The point I was trying to make, is that an RF ground and a DC ground for lightning, are not the same thing.

All my feeds come to a copper panel, where gas discharge tubes take them to ground. The shields are grounded there, but not in an RF sense. The HF vertical has it's own counterpoise, which is elevated, and the higher band antennas are yagis, and the discone, which don't need or want an RF ground.

In a practical sense I would agree, but the FCC wouldn't. Intentional
emission is just that.
Basically, you have to put SOME signal up the pipe, to check the impedance.

You could use a TDR, which uses single pulses, but that's pretty expensive,
and still emits.
I don't know of any way to measure impedance, using DC.

Been there already and done that Cecil. 'Bout a half century ago. An end-fed Zepp is simply a VOLTAGE (vs. coax fed) RESONANT dipole Cecil which should also work OK on it's harmonics if done right. On precisely which MF/HF ham band(s) bands is a 414 foot long wire resonant as a half-wave dipole and/or multiples thereof Cecil?? Wherin obviously lies the guy's whole problem. You go back and read the book again Sweetums.

Maybe you missed Walt's point about using low loss feedline *with* a tuner, and accepting the modest attendent reflection losses as a minor concession to operating ease and flexibility. If you use a single dipole for each band (or for harmonically related bands such as 40 and 15 meters) and a rig with an autotuner, and use a good quality low loss coaxial feedline, you will be able to operate across all of each band without concerning yourself with the loss in the feedline. Of course it will be present, but it will be insignificant from an opertional standpoint. Use of a manual tuner isn't as convenient but is no less functional.

If you are concerned about maximizing radiated power and conserving every transmitter watt, you will complicate your installation considerably, at least initially. The guy on the other end of the QSO won't be able to notice the difference.

It's a good argument generally, but not in this case. It isn't that the quality of stock has changed so much, as the composition of the inventory in the first place. If you had walked into a RS store in the late 70's, you would have found walls and drawers of parts, and few phones or gadgets or toys. The business model changed, as they say. I don't mind that so much. What bugs me is that RS *advertises* they have things they almost never do (and I am not talking about the special order merchandise indicated by red or blue in their catalog), like a 47 or 6.8 ohm 1/2 watt resistor, two of the most common values used in all electronic circuits. Or 50-ohm coax. Or regular UHF plugs (not the crimpers for 58/59 coax).

A 40m dipole centre fed with 50-ohm coax (a choke balun is not necessary) will not do very well on 80m and there's not much you can do about it.

But you could turn it into a T-antenna by strapping the coax conductors together and tuning the bottom end against a good ground. That will probably do a good a good job on 80m and will not take long to set up a trial.

Hi NG!

I always tought SWR was affected by coax length, and the metal surface right below the antenna. But now most ppl here tell me it's not.

My problem is that I have my antenna at the spare tire behind my vehicle (4x4). But the SWR is in the red zone. I can't get it down a lot by only tweaking the antenna tip. Is SWR realy only affected by the length of the antenna itself? What else do I have to try to get a better SWR? (The range is not realy the issue here, I will only be using the CB on small 4x4 terrains and with 4wd autoclub days.)

With regards,

Vincent

As some of the other posters have indicated, there is not much information with this question. The answer depends mostly on two things: 1) How electrically short is the antenna? and 2) What type of antenna?

When an antenna is truly electrically small, it generally exhibits the behavior of an electrically small loop or an electrically small dipole.

As the operating frequency decreases below its primary resonance, a dipole or monopole antenna will exhibit decreasing radiation resistance (it approaches zero) and increasing capacitive reactance (it approaches negative infinity) - it is capacitive.

A loop antenna behaves differently. As the operating frequency decreases below the loop's primary series resonance, it will first exhibit capacitive behavior until a point where it exhibits an anti-resonance - the radiation resistance and reactance are very high and the reactance quickly becomes inductive. With further decreasing frequency, the radiation resistance decreases and approaches zero. The reactance remains inductive but it decreases and approaches zero as well.

To exhibit loop behavior, an antenna generally must have some portion of its structure shorted to ground. A folded monopole is really a compressed loop not a monopole. A normal mode helix, while looking like an inductor, exhibits monopole behavior.

Wonder if your antenna is mounted on a fiberglass cap? Mobile installations can be very tricky because parts of the vehicle may be in close proximity to the radiating element (a source of detuning) and because of groundplane irregularities. Whenever possible, it's best to mount the antenna on top of the vehicle. If you have a fiberglass cap, consider using a 1/2-wave mobile antenna that doesn't require a groundplane in order to function. If you do use a 1/2-wave antenna, consider installing some ferrite beads at the feedpoint to keep RF off the feedline. Hope that helps.

Wow, Richard,

I presume HL&P is your utility and they haven't yet tumbled to the fact that
running the ground wire inside metallic conduit negates lightning protection
unless it is bonded to the conduit at both ends? Even the backwards CPS
here in San Antonio figured that out a number of years ago.

Hi, tnx for your reply.

> Wonder if your antenna is mounted on a fiberglass cap?

It's mounted with a metal cap. This thing is mounted in an excisting
hole in the spare wheel carier. The carier is also made out of metal,
and mounted directly to the vehicles grounded carrosery. Ground should
be ok. I measured voltage between taillight and the ground of the
antenna mountpoint. That gave the dame reading as when measuring between
TL and ground of the TL.

> Mobile installations can
> be very tricky because parts of the vehicle may be in close proximity to the

> irregularities. Whenever possible, it's best to mount the antenna on top of the
> vehicle.

The entire top (backend) of the vehicle is polymer material (plastic)
and glass. The only metal parts are the lower part of the backdoor and
the spare wheel itself. As where the antenna is, only the fisrt 2 inches
are somewhat surrouned by metal.

The other remark, groundplane... How does this affect the SWR? As you
can understand, where is not much of a metal plate underneath the
antenna when mounted on the spare carier...

> If you have a fiberglass cap, consider using a 1/2-wave mobile antenna

Steve, VE9SRB wrote:
"A loop antenna behaves differently."

Steve is right. I assumed a straight wire antenna.

There are other configurations. Wrap a dipole around until its ends almost meet and you have an open-loop antenna. It looks capacitive when too short, as a straight-wire antenna does when too-short means at a frequency below first resonance.

Then, there are yet other antenna configurations, slots, discones, and fractals, for example. We had a simple question which incited simple answer from me. Maybe too simple.

I don`t see why: "To exhibit loop behavior, an antenna must have some portion of its structure shorted to ground." A small (too short) closed loop tends to have nearly constant current and exhibits bidirectional behavior with or without a ground connection.

Best regards, Richard Harrison, KB5WZI

2557. Broadband Tank Circuit Question

Source record: 154160
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc,sci.electronics.design

I am gathering info to build an HF amplifier but have not been able to find a good design for a truly braodband tank circuit. I know that the amp will always be used with a tuner so it makes sense to make the amps output fixed at 50 ohms or close to that over the full range of each band. I suppose a resistor would do but then there would be the power considerations.

Tnx

I'd just go to Radio Shack and buy one of their portable, indoor TV/FM antennas.
They have a dozen or so models in all price ranges. (The TV channels straddle
the FM broadcast band, so anything that receives TV should get FM, too.)

You could build something, but it'd be more trouble than it's worth.

>I always tought SWR was affected by coax length,

That's a common belief, but it's totally untrue. While the type and length of your coax can affect the loss your antenna system suffers from, it will not change your SWR's.

Dave Van Horn wrote:
"In a practical sense I would agree (bridge generators used to measure antenna systems is not "going on the air"), but the FCC wouldn`t."

FCC rules are not my favorite reading, but they usually are practical. Rules seek to avoid interference.

Transmitting a tiny signal as needed for measurements of an antenna system is likely legal if done so as to minimize interference. Commercial services check their antenna systems with bridges. They are duly licensed to use an assigned frequency which reduces the interference exposures and in some cases are limited in the time at night when they can be testing.

Using a bridge on an antenna system exposes the bridge operator to harmful interference too. The broadcast operator does his measurements in the early morning hours when most other stations on his channel might be off the air, though that doesn`t happen so much any more. The shortwave broadcaster tries a bridge measurement to see if interference is low enough to get a good measurement. If he were lucky, he would be measuring above the maximum usable frequency or so far below the optimum working frequency that extreme attenuation would give him a clean slice of spectrum.

The FCC is charged with promoting radio utility. It was never intended to inhibit the use of radio. Where commercial 2-way radio services are required to share frequencies, the rule is : listen first, and if the channel is vacant, then use it. That is the amateur rule too, I believe.

For practical reasons, the FCC does or should allow bridge signals on antennas when they are non-interfering. If I am wrong, I am sure somebody will correct me.

Best regards, Richard Harrison, KB5WZI

Vincent,
The length of the coax feedline can affect the
readings of an SWR meter, but not the SWR of the
antenna system. If the antenna and feedline aren't
of the same impedance the result is a higher than
1.0:1 SWR. This SWR doesn't change unless there
is some change made to the impedance of the antenna
or the feedline. The impedance of a feedline does
not change because of length. The SWR measured at
the antenna / feedline junction isn't necessarily
what you will see if you measure SWR at the radio
and feedline junction. If you measure SWR at the
radio you are reading the antenna 'system's SWR,
the combination of antenna ~and~ feedline.
The SWR read at the antenna / feedline junction is
the SWR you should be concerned with for maximum
efficiency of the antenna. The SWR read at the radio
determines how much power the radio produces. The
radio won't produce as much power if it 'sees' a
high SWR (an antenna system impedance it doesn't
'like'). The SWR reading at the radio end of the
feedline and the SWR reading at the antenna end of
the feedline are the same when the antenna's and
feedline's impedances are the same (the ideal). So
you can see that the length of the coax doesn't actually
change the SWR, it only 'fools' the meter.
You didn't say what ~type~ of antenna you were using,
that can make a difference in ~where~ the best place to
mount it is.
This is too long now, so I won't go into that...
'Doc

The FCC does permit small non-interfering signals to be radiated. This is covered in Part 15 of the FCC rules.

You need to know the complex output impedance of the amplifier across each band and then devise a circuit that best matches it to 50 Ohms. Alternatively you can just get it closer to 50 Ohms, and rely on the tuner to do the rest. Keep the coax run between the amplifier and tuner as short as possible if you want to maximize the bandwidth.

Everyone has differing opinions on this I am sure. For what it is worth, this is mine.....
I have ordered from R & L Electronics often, sometimes the best price, often not, but the customer service at R & L is very much like your hometown shop down the street where people seem to remember your name and actually care about your buying experience.

Not dissimilar, I have dealt with AES often too. They have a much larger selection of parts and accessories than R & L and are a much bigger operation, not quite as "hometown" like but they still seem to care about your satisfaction.

To date, I have made several purchases from Texas Towers, I have not had the "hometown" experience with them, but they have always honored what they sold, and yes, they often have the best price around.

HRO, they are a hometown dealer of sorts for me. They have a location less than two hours away that I have often visited and I have ordered from them by mail as well. To me, they act like they could care less if I bought anything from them or not. When in their store in person, they have three clerks just hanging around doing nothing and do not try and help out at all. They may honor their warranty but I will not buy from them under any circumstances anymore... and by the way.... I have a lot of friends that have had a similiar experience. If they have a product for $20.00 less I promise you I will pay the extra $20 somewhere else or do without.

Sincerely,

Patrick de W4PHM

Crazy George wrote:
"---running the ground inside metallic conduit negates lightning
protection unless it is bonded to the conduit at both ends?"

Yes. Steel conduit creates inductance which opposes lightning current.
This is mitigated by using the conduit itself as a lightning conductor.

HL&P`s focus is on protection of the ground connection from abuses. So,
they say, if the conductor is aluminum it must be insulated (I suppose
for the physical protection given by the insulation). If it is copper
and not in conduit, it must be a minimum of #6 and be securely attached.
A smaller #8 conductor may be used if it is armored or in conduit (for
protection).

HL&P has smart lawyers reviewing its publications to minimize its
libilities as regards its practices and what they say about them.

Best regards, Richard Harrison, KB5WZI

It depends where you are in NH. I was in Portsmouth from 1985 to 1990 and had two 10' ground rods in the ground. No, I didn't get them in at first try because of the rocks but it's not like there is a solid slab of granite under every square inch of Cow Hampshire. I finally did get them in and only inches from where I originally attempted at first. Just find the right spot.

I have four ten foot ground rods. Two are copper-clad
steel; two are copper pipe. I used to frequently have to
wire brush and refresh the connections where the ground wire
was clamped to them. NO MORE!! I removed the clamps,
silver soldered the connections and have been worry free
ever since.

Well, I'm actualy happy with the long version of the explanation. I understand a bit more now. I don't know what the brand and type of the antenna is. I got it with the CB radio. It's about 1m50 long. Looks like it's a metal cylinder with a black polymer coating. At the top there is a screw that holds the tip in plae. This tip can be extended or retracted. (sory, not my best english here, I think). At the bottom there's a half sphere, that can be mounted to the other half, wich is the mounting point on the vehicle. (this mounting-thing comes with 13 in a dozen).

Well, not entirely true. Try 200ft of RG58 on 440MHz. You can leave
the coax open at one end and get a decent SWR at the other end. :-)
Only lossless feedline doesn't change SWR from end to end.

Does anyone have the frequency and power range specs on a M.C. Jones Electronics Co. Micro Match Model number 576.8 directional power unit? It has two diodes mounted in the top - I assume one for forward and one for reverse or possibly for two power ranges ?? I also need to know if the unit is meant to drive a 30 ua or a 100 ua meter movement - or possibly some other meter.

Any help would be greately appreciated.

2572. Re: Butternut HF2V + SGC SmartTuner = All-band vertical?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-23 21:23:18 UTC
From: Per Enocson <per.enocson@telia.com>
Message-ID: <a7zL7.67$jY3.16578@newsc.telia.net>
Source record: 154284

Hi Rick/David,

I have an HF2V on the roof of my house, at about 20 feet, fed with 10 mtrs of 50 ohm coax, 4 each of radials for 40 and 17 mtrs.

I get excellent results on 40 and 17, plus quite good results on 80,30,15 and even 12 m, when using my MFJ 971 tuner. 20 m is tough as the vertical section is a 1/2 wave.

I believe that if you feed it with ladder line and use an autotuner, the results would be quite acceptable on all bands 80-15, when getting higher in fq think you will lose the long angle radiation as the vertical part is getting too long (according to the ARRL antenna book).

I was positively surprised to be able to use my HF2V as a trapless multiband antenna, guess it is succesful here as the coax is short and the losses thorugh mismatch at the antenna base therefore acceptable.

So I m going for an autotuner and additional radials for 80 and 30.

Maybe this can be of some help for you Rick. In any case, it is an excellent antenna for 40 and, surprisingly, also for 17 m DX.

Good luck / 73s de Per SM0WRA

You might have to keep an indoor antenna several feet from the
computer/monitor as well, since many monitors will radiate a signal that
will interfere with VHF reception. As others noted, you can use a simple
switch to go between the FM and TV card inputs; or you can use a VHF
"splitter" to do the task.

Irv,
Soldering the connection doesn't hurt, but without
the clamp you do not have a good connection. A soldered
connection doesn't stand up to a surge more than once
without melting. Using a mechanical connection, like a
clamp, will take more than one surge. NEC calls for a
clamped connection, and that's why.

In general coax length doesn't affect swr but there are situations where it can. I have found where removing as little as 3 feet of coax from a feedline making the difference in a high swr and a flat one. I am assuming it just happened to be a multiple of the wave length.

Bill

This is an indication of mismatch but as you see you can finagle it to
your advantage as long as you understand why/where the mismatch is
occuring. Otherwise you may simply be loading up a damaged piece of
cable.

Hi Richard:

My statement is not generally correct.

I was specifically thinking of antenna configurations that require some form of ground structure to "work against" - such as monopoles, folded monopoles, Inverted F antennas, etc. Sorry for the confusion.

Without the ground requirement, the antenna structure would have to be "closed" in order to behave as a loop when electrically small. The folded dipole being an example. It is a loop antenna being very compressed in one direction more so than the other.

The swr does not change on an open line , shorted line or anyother line. What the common swr meter reads will vary with the line length. Teh very long length of lossey line will show a low swr on a common swr meter. If the losses of the line are factored in , the swr will be very high. As always the fractional parts of a wavelength of line can alter the swr as seen by the transmitter but the swr at the antenna end will not change with line length.

No such thing as a "broad band tank circuit" A tank circuit implies energy
storage
such as used with a class C amplifier. As such it is narrow band. Other types
of amplifier operation can be coupled with a matching circuit and maybe a low
pass
filter.

What type of amplifier are you planning?

Thanks Doc! I needed that!

Actually I have wondered about that. There is, however
somewhat of a mechanical connection in that I have the #6
copper which links the four rods wrapped tightly around each

rod prior to the silver soldering. Does that sound better
or is it
still a weak link?

I don't have the exact model to function listing for those things, but there were a large number of different models built into various pieces of government equipment from HF to UHF. As far as the meter is concerned, the scale is the usual Micro Match non-linear, and there was usually a trim potentiometer anyway, so the more sensitive, the better. Your best bet is likely to characterize it yourself using whatever frequency transmitters and powers you have available. I never heard of any very sensitive and therefore easily damaged models, so I expect 10 watts would be a safe place to start testing.

I am presently restoring a MM-414 indicator panel which has 4 watt and 12 watt ranges, and uses a 200 uA meter, for example.

You didn't mention if it's a solid state amp or a vacuum tube one.
For solid state, have a look at the work Helge Granberg (sp??) did
while at Motorola (Lots of ap notes!)...or see any number of other
references. For a vacuum-tube amp, if you use a tuned tank, you're
stuck with some minimum Q; but if you put a broadband transformer in
the circuit, you could get to rather a lower Q. Mind you, you may not
really WANT all that low a Q! Depends on what you're trying to
accomplish. But you could put in a 9:1 or even 16:1 broadband
transformer and have to match a much lower impedance ratio. I'd for
sure put the transformer at the output of the tuned tank. Do you have
any reference books to help you out? BTW, the old Central Electronics
rigs used cathode-follower outputs, as I recall, for broadband output.

Cheers,
Tom

I ordered a new 7100 from them and got a used one, that is one that was broke and had been sent to the factory. Called and they shipped a new one but said the would hold the ticket until they received the used one. Turns out they did charge my card and I had to call to have it took off. The new one they sent worked two weeks and went dead. I called and was told to send it to the Factory. No more for me at Texas Towers .

Source record: 154289

Vincent,
Okay, you asked for it! (LOL) Your antenna sounds a lot
like a helically wound antenna, maybe made by 'FireStick'.
With antennas that have a 'loading' coil at the bottom or
in the center of it, it's best to mount the antenna in such
a way so that the coil is above the roof line of a vehicle.
Any metal near the coil interacts with it to change it's
electrical characteristics, and the state of 'tune' of the
antenna. It can make the antenna seem too long, or short,
and changes it's input impedance to some extent. Helically
wound antennas are all coil, so they are affected to an even
greater extent by surrounding objects (not just metal). It's
best to mount a hellically wound antenna completely in the
clear. That's not always possible, so you have to compromise
as to how an antenna is mounted. The more of the antenna
thats above the roof line of the vehicle, the better it will
work. The higher the antenna is mounted, the more it will
hit things too (trees, awnings, etc.), so you have to decide
about that.
A mobile antenna except in a very few cases, uses the
vehicle body as the 'other half' of the antenna, or as ground.
That means that the mount must be well grounded/bonded to
the vehicle's body and/or chassis. It also helps if the
antenna is mounted symmetrically in relation to the vehicle so
that it has equal body area in all directions. Thats another
one of those 'ideals' that you can only get close to, in most
cases. Mounting the antenna in the center of your 4X4's roof
would cause all kinds of problems for you (you would hit
~everything~ you drove near LOL), so you pick a spot that is
the best compromise for you.
The 'screw tip' of your antenna is for tuning. Actually,
it's for adjusting length for resonance, but it also serves
as a way of matching input impedance to the feedline. To adjust
it correctly, check the SWR on channels 1 and 40, and note them
for reference. If the SWR is lower on channel 1 than on 40,
then the antenna is too long and the screw adjustment should be
turned so that it is further inside the antenna (just a few turns).
If channel 40 is lower than 1, then the antennas is too short
and the screw should be adjusted out a few turns. After each
adjustment, check the SWR again. When you reach a point where
channels 1 and 40 are about equal in SWR, channel 20 should be
the lowest SWR possible (may not be very low). Your antenna is
then tuned as best as it's mounting location will allow.
A little about SWR. An SWR reading of 1.5:1 or lower is

really about as good as you need worry about. There is no real
or practical difference between a reading of 1.5:1 and 1.0:1 in
the 'real' world. Once you get the SWR as low as 1.5:1, quit.
You will see no noticeable by trying to make it 'better'. SWR
changes according to what is around the antenna when it's checked.
If you watch the SWR while your driving and passing other vehicles,
trees, buildings etc, you'll see it change quite a bit in some
cases. That's normal and you shouldn't worry about it much. You
can do more harm by continually adjusting the antenna than a slightly
high SWR will ever harm your radio or it's performance.
That ought to keep you busy for an afternoon Vincent. I hope
you get things adjusted to your satisfaction, and good luck.
'Doc

Of course it does. Except for lossless lines, the forward power decreases
from the transmitter to the antenna and the reflected power decreases from
the antenna to the transmitter. Thus the SWR is highest at the antenna
and lowest at the transmitter. As I stated, a 200ft piece of rg58 used
on 440MHz will have a virtually infinite SWR at the open end and a
relatively low SWR at the transmitter. This effect exists in all real
world transmission lines.

Irv,
I guess it just depends on how serious you are
about having a good ground. As you have it, it'll
probably work as well as with the clamp. But, theres
another consideration you might think about. If you
ever have to defend yourself in court (not as far fetched
as you might think), having a ground system that conforms
to the national standard ~does~ make a big difference!
Also, if there is enough energy transfer through the
solder joint to melt the solder, more than likely it
will also deform the wire it's self, which will loosen
it, and then you have an intermitant connection.
So, it's really up to you. It very seldom 'hurts'
to be careful, but you can't say the same for not being
careful...
'Doc
PS - 9 times out of 10, if you get a surge large enough
to melt a solder connection, you will be very lucky
not to loose at least part of your equipment. You
just can't mess with 'moma-nature' and get away with
it...

Right on. In 40 plus years of hamming I have only had one
friend suffer a direct hit -- it took out plenty! There
really isn't much you can do against a direct strike except
pray unless you want to spend a bundle, and then there is no
guarantee! I always do a physical inspection when I'm out in
the yard, just in case. The main idea of the rods is as a
tie point for radials and other copper lying just below the
grassline! Every once in a while, when I'm not fishing or
engaged in other important activities, I bury another line
out back. I don't have a fancy system -- an R7 mounted on a
pipe out by the garage, which doesn't really need any
elaborate ground, and a 30 ft lodgepole pine (the pole only)
with a yardarm and some pulleys from which I can easily raise
and lower a number of wire antennas (usually verticals) which
I experiment with. Right now it supports my 2m J-pole, and a
trapped inverted L for 40/80 meters. The radial plane is
mainly for that one. I live in a side by side duplex and
can't put up anything too elaborate -- but
I can make some pretty efficient antennas very cheap -- the
buried copper makes up for a lot of sins.

I used to have a very fancy shack, a tower beam and rotor,
and two stations -- one K'wood, the other Yaesu. I dumped it
all a few years ago and reverted to a little K'wood TS-520S
and my wire antennas, plus any old antennas I can pick up
used or broken. It keeps my fully occupied, happy, and off
the streets at night! :-)

Source record: 154295

Assuming your antenna is not screwed up, shorted, or grounded with a bad ground, it is all about impedence matching.
Your antenna is probably a baseloaded quarterwave vertical, common antenna for cb, magnet mount?
Anyway, at the resonant cb frequency, its impedance is around 35 ohms or less. Your cb is 50 ohms unbalanced. You gotta match them.
So, what happens with the the coax.
If the impedance of the of the antenna is 50 ohms, and the impedance ot the coax is 50 ohms, any length of line will always read 50 ohms at the transmitter end.
If the antenna is not 50 ohms, ie 35 in this case, a halfwave length of 50 ohm coax will pass the impedence of the antenna and will read 35 ohms. Any other length will not pass the 35 ohms, and it will read some other impedance at the transciever end, and thus various swr's are measured. For the resonant frequency of the antenna, probably the middle cb channel, there is a length of the coax somewhere between a quarterwave and a halfwave that will transform the 35 ohm impedance, or whatever it is, to 50 ohm impedance, and the swr at the transmitter end of the coax will read 1.
Then what happens is as the cb is changed from channel to channel, the frequency changes, and so does the swr because the antenna is now not quite resonant on all the other channels.
It is usually close enough for the cb transciever to load the antenna though. Since it is close enough when matched with proper coax length to the center channel, there is really no need to do anything else, since it is mobile and you dont want to be fiddling with it when driving.
Other things to do:
Measure the impedance at the antenna at the resonant channel, adjust the antenna so the resonant channel is the center one, 20 I think.
Then, knowing what the impedance is, install a matching balun transformer, ie 2:1, 4:1 or whatever it is to transform the impedance to 50 ohms at the antenna. Now, it doesnt matter what length the coax is, the 50 oms will be passed to the transmitter. When changing channels, the impedance will change a bit, the new impedance will be transformed to a different value, and the transciever will see swr on the other channels, but probably not high enough to make a difference.
The next thing to do is install an antenna tuner at the transciever between the transciever and the coax, and tune it so at the other channels, the transciever sees 50 ohms.
If it was me, I would first check all the parts such as antenna, coax connectors, etc to make sure everything is in good working order, not corroded or anything, then I would mount the antenna, tune so it is resonant at the center channel of the cb, then cut the coax so it shows a 50 ohm impedance at the transmitter end of the coax. I would then screw it to the cb and leave it alone.

wh

Steve, VE9SRB wrote:
"Without the ground requirement, the antenna structure would have to be
"closed" in order to behave as a loop when electrically small. The
folded dipole being an example."

I infer that Steve is saying we need a completed circuit between the feedline and the antenna. Agreed. It is also true that a folded dipole is a deformed, compressed loop, as Steve says.

The folded dipole is notable for the fact that its first resonance is at a frequency where its length, tip-to-tip is about 1/4-wave. That is because at that length its perimeter is about 1/2-wave. There is a collision point for current exactly opposite the feedpoint, a short-circuit, in effect. This produces a high impedance 1/4-wave back at the drive point.

The open-ended dipole experiences its first resonance at a frequency where its length, tip-to-tip is about 1/2-wave. That is twice the frequency at which the folded dipole undergoes its first resonance. This means that the folded dipole undergoes twice as many resonances as frequency is increased as does the open-ended dipole.

A small continuous loop (inductive and below first resonance) can be sliced open directly opposite its feedpoint. Its pattern is unaffected but its impedance switches from an inductive low resistance to a capacitive high resistance. It is a dramatic shift from nearly a short-circuit to nearly an open circuit.

Best regards, Richard Harrison, KB5WZI

If the antenna impedence is 35 ohms, and you are using 50 ohm coax, what
is the swr shown at the transmitter?

Larry, WB7UCF wrote:
"Now how "long" of a ground can we get away with?"

If your radio is near the earth and your ground wire is short in terms of wavelength, the fraction of generator voltage dropped across the ground wire should be small. The r-f voltage between radio and earth should be small too given that now "we`ve got our ground" and the connections are all good.

How long your ground wire can be depends on wavelength.

You might have problems if your radio is on a higher floor and connected to your good ground by a 1/4-wave ground lead. It`s better to have a 1/2-wave ground lead which would repeat the low ground impedance of the good ground connection we worked for.

The necessity of a good r-f ground is much greater when it is part of an unbalanced antenna system. If your antenna system is balanced, you may only need an r-f ground to rid yourself of stray r-f.

I don't understand this obsession for using coaxial
feedline for impedance matching. If the transmitter's
output impedance is 50 ohms, the feedline's impedance
is 50 ohms, why not just make the antenna's input
impedance 50 ohms and have done with it? It really
isn't that hard to do at all. Usually requires maybe
three parts available at any Radio Shack, depending on
how 'handy' you are maybe an hour of your time (call
it two hours), and some simple hand tools (drill, drill
bit, bolt, couple of nuts, soldering iron and a 'Dixi'
cup and a 'twist-tie'), a couple of wrenches, and an
SWR meter. It'll work on almost any non-base loaded
antenna.
I ought to go into business...

That gives a reactance of ~152Kohms at 550KHz, ignoring shunt capacitance, #14 wire will handle tower lighting current.

The choke could act as the series element in a pi-network for lightning isolation at other sites. Broadcasters don`t get lightning back on their a-c service from frequent direct hits to their towers, thanks to the tower lighting chokes. The broadcaster only effectively has an L-network since the capacitance on the tower side of the choke is very small. It is still a lightning stopper. In several hundred other locations I`ve used the chokes in pi-networks to stop the lightning. Every wire including the neutral has to have a pi-network, but it stops the lightning.

Hi all,

Just erected a 6-meter 3-el. Yagi. The resonant frequency is slightly lower than desired. In order to raise the resonant frequency, should I trim ONLY the driven element, or should I trim ALL 3 elements? I am planning to scale the antenna using the formula:
[new length] = ([resonant frequency] * [old length]) / [desired resonant frequency]

Any advice on this question will be very much appreciated.

Thanks for the info, George.

It is interesting that the Micro Match meter movement that I have that came with this sampling unit is scaled in a 4 watt and a 12 watt scale and a SWR scale. Maybe we've got the same meter movement. Mine is 200 ua full scale.

I use mostly HF equipment and when I play with this unit and compare it to my old Bird 43, it doesn't seem to track very well. I guess the only thing it could really be used for is, like you said, with a pot and set it full scale and read SWR off the bottom scale. I may never know the power and frequency range it was actually built for.

Thanks again,
David Beard

OK, I'm looking to put up a multi-band wire antenna in the trees in my backyard.. Here's what I'd like to do.. I want to get several large plastic coffee can lids and make holes every 3 or 4 inches around the edge, then run a wire thru each hole.. Each wire will be for a different band. Has anyone ever seen anything like this and will the different wires help with the wire I'm using at the time?? Say I'm on 40 meters and have 10, 12, 15, 17, 20, 40, and 80 meter wires.. Will the wires other than the 40 meter wire help with my signal strength?? Will they help in any way at all?? Ideas and comments are welcome.. The wires will be suspended in as close to an inverted V that I can manage if that helps..

2607. Halo type antennas for HF

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-24 11:10:47 UTC
From: A Swiffin <a.swiffin@lineone.net>
Message-ID: <3bff844c_1@mk-nntp-1.news.uk.worldonline.com>
Source record: 154311

Hi,
After quite a number of years I'm planning a return to HF and
am looking at antenna designs. I've seen a web site describing
the 'Cobwebb' antenna which claims great things and interests me :
http://www.g3tpw.ukgateway.net/

This antenna seems very similar to 144Mhz Halo antennas in that a
half wave dipole is wrapped round into a square, like a quad but without
the ends touching. I'd like to do some of my own experimentation with
this design so I'm hoping that some of you antenna experts here could
point me in the right direction on some points:

a) what does folding a half wave dipole round like this do to its radiation
resistance, does it lower it from the classic 70 ohms of the dipole?

b) is this why 2M Halos use a Gamma match to connect the feed, am I right
that a gamma match is usually used to match 70/50 coax to a lower impedance
i.e. a yagi driven element is usually much lower unless folded (The
classic
300 ohm folded impedance becomes more like 50 when used in a yagi??)

c) Can anyone point me to practical designs for an HF Gamma match which
I could use with this kind of design- references to good books etc.

I expect I could ask a whole load of other questions, but this will do for
now!

Need more info. How are you measuring the resonant frequency? Is the
antenna mounted suitably for testing so as to give reliable results? If
you're judging solely by swr reading it may be a matching question as
opposed to a dimensional question. What kind of matching are you using?

If you have a 40 meter wire you really don't want a 15 one. In that
case they are both fairly resonant on 15 (1/4L and 3/4L) and will be in
parallel on 15 and that will probably screw up the match on that band.
I think the same may apply on 80/10 depending on your dimensions.
Apart from that, there is little interaction bad or good between the
non-resonant wires. I've never personally thrown 12 and 17 meters in
the mix but I think they should be ok.

> It really won't matter too much, using an antenna
> at half it's fundamental frequency doesn't work too
> well. Using a tuner may help, depending on the 'range'
> of the tuner.

In an old book I have there's quite a nice table showing
the impedance presented at various wavelengths, the
values show the resistive, capacitve and inductive
components:

Wavelength Resistive capacitive inductive

1/4 12 -1000
1/2 70
3/4 1000 +1000
1/1 5000
5/4 1000 -1000
3/2 90

The book says the L/2 and 3L/2 are usually near to these
values but the other reactances can vary widely depending
on the element diameters.

Which shows why you can get away with a half
wave dipole for 40 on 15 metres where its a
one and a half wave. But a 40 metre half wave
on 80 presents 12ohm and -1000 capacitive - should
be fun to tune :-(

No, that's not correct.

The old CE rigs (100V, 200V, 600L) achieved no-tune 50 ohm output with
conventional-looking tube circuits. The trick was the use of special patented
tuned circuits. The patent should still be available from the Patent Office
website. Home construction of one would be legal because the patent ran out
long ago.

Paul,
It should work fine. Except for thespecifics (coffee
can lid for spacer) it sounds like a typical 'spider', or
multi-dipole antenna with a common feed point. The close
spacing of the elements will affect resonance of each of
the individual dipoles to some extent, but it isn't a 'big'
problem. Give it a 'shot', see what happens...

Jeffrey,
It ought to work fine by just trimming the driven element. Even if the resonant frequency is 'off' by the width of the whole band, the amount you trim to change frequencies is going to be small. Since the relationships between driven and parasitic elements really isn't that critical, I'd leave them alone.

I think perhaps the coffee can lid may not have the strength you need. I suppose stacking several would help, but still wouldn't last long.

I have seen plastic oil cans and plastic antifreeze cans used successfully as end insulators.

Consider the role a Balun might play in preventing you feedline (coax?) from radiating power that may cause rfi/tvi.

I've seen doublets in use that work very well.

Wires that close together interact and you will have a devil of a time tuning the thing. Start with the lowest band and go up in frequency. Be prepared for a long afternoon.

Save yourself some time, and wire, just use one dipole, feed it with ladder line and use a tuner. You can hang it as inverted V or inverted L. The L will help even out the lobes that develop at higher frequencies. I use a top fed inverted L, 51 feet on a leg, top is 60 feet high in a tree. Works fine on 80-10, it even loads on 160.

Try some form of spreaders like plastic popsicle sticks. Those lids will
present a pretty good wind load which you might want to avoid.

As short and direct as possible.

>Any thoughts on using RG-8 a a "shielded" Ground wire?

The braid from old coax may be useful for indoor use as a flexible jumper from a piece of equipment to a ground point, but that's all I'd use it for. To bond to the ground rods, seek out heavy copper wire (I use #6) at Home Depot or its local equivalent. Often end-of-roll scraps can be had for a discount. Multiple-conductor house wire (NM or UF types) can be cut apart for the individual conductors.

Hi Andy,

I would suspect almost any reference you follow could be extrapolated to real values. I say this because a short hand for the capacitance has often been stated in terms of the band. That is 4 or 5 times the band in meters. Hence the gamma match cap for 40M would be around 200 pF. For 2M perhaps as small as 8 pF. If I were to eyeball any particular gamma match section by simply viewing an ad, I would speculate that the matching section rarely exceeds 1/4 the length of the element it is matching - if that long. I can't imagine it running parallel at more than say 2 to 8 inches away.

As such, I am not particularly in tune to any particular optimal or even resonant solution first time. I use a variable cap knowing full well that any computation will have enough error to invalidate a fixed value. And given my vague approach to sizing the matching section, that cap will slop enough to fit.

Even for a 40M design, the tolerances and values required are not very monumental and given the variety of installation and environmental issues that complicate design, are quite accessible. Still and all, find a more authoritative source than this scribbling.

Rather than soldering, you can also use CadWelds. They will weld the
ground wire to the rod.

Source record: 154093

Tom:
Yes, but aside from the connector adapter needed, there is another consideration, overload. The auto receiver was designed for optimum performance using a short rod antenna. The yagi is going to present much stronger signals to the front end of the radio, and you may find that the front end or mixer overloads, and you hear fewer wanted weak signals, and a lot more intermodulation products from the strong signals. To sort them out, you will need an adjustable attenuator to balance the amount of energy you pump into the receiver against where it overloads.
Good luck; BTW RatShack has the adapter(s) you need, but the attenuator will have to be found somewhere like a ham swapfest, unless you want to use a bunch of fixed attenuators and connect/disconnect them as needed.

Larry H in Seattle has e-mailed what seems a copy of a posting which in part says:
"I once read an article in "Popular Science" that said the size of a ground (Diameter of wire) only matters if directly hit by lightning."

It seems a ground rod may have been intended, not just a connecting cable. Inductance and skin resistance apply to both connecting cable and ground rod with some minor differences.

Current in lightning flows through the earth. It is most intense at the earth`s surface and declines with depth in part due to "skin effect" in the earth as lightning is a transient with much of its energy at low and medium radio frequencies.

The higher the frequency of r-f energy, the less the depth of penetration. Most of the energy in a lightning stroke penetrates at least as deeply as a common ground rod, by the depth at which current is attenuated by a factor of one neper, which is the definition of 'skin depth'. Poor soil conductivity results in deeper penetration as the current finds a way around sorry surface soil.

A large portion of the lightning`s energy is at low and medium radio frequencies. These penetrate much more deeply than a common ground rod so none of the ground rod`s depth is wasted in making contact with the soil. It is all useful.

Surface area of a ground rod is important in reducing contact resistance with the soil. Surface area is a product of length and circumference. Circumference is pi times D.

"Popular Science" may say that ground rod diameter or ground cable diameter only matters in case of a direct hit by lightning. Well, a near miss might produce excessive current too. True, you only need a fire extinguisher if you have a fire. Also true, that you don`t need high current capacity when you don`t have high current. I suspect the Popular Science author had in mind that static drain is possible through a high resistance because its accumulation rate is slow.

Best regards, Richard Harrison, KB5WZI

Gary,

I would use LMR-400. It beats Belden-9913 and is much easier to work with and
less expensive as well. Ty KF4DLA Then again, I work in a two-way radio shop,
so my opinions may n ot be valid.

Do you really want the added receiver noise? ...

You need to monitor the voltage at the rig and compare the standby voltage with the transmitter keyed voltage. Also, you need to determine the total current draw for all devices on the circuit. If you are seeing a large voltage drop when you key the rig, then the circuit is already close to "maxed out" without the transmitter keyed.

If this is the case, you will need to either eliminate other sources of current draw, or re-wire the room for a higher level of service. A 15 amp service is typically run for bathroom or bedroom use. For your radio room, you should really think about at least 25 amps @120 vac, and possibly a 15-20 amp @220 vac line also.

You might want to try something other than coffee can lids, they break down pretty quick due to UV. Maybe a plexiglas or fiberglass rod instead. Hate to see you go to all the work and have the spacers fall apart in short order.

==========
This effect of RF in the shack is probably not uncommon. I had it for a period in another house, in the bedroom, on 100 watts on the 15 meter band.. When the key was down the room lights were slightly brighter. The lights flickered when on SSB. The dipole antenna was not very high above the roof of the house.

The effect was obviously caused by RF currents induced in the house wiring due to proximity to the antenna. Nothing to do about it but change the antenna orientation or shift it further along the back yard. Or rewire the domestic power distribution system. Or take your pick. Or in my case not to use the 15m band.

During daylight with house lights switched off there was never any trouble. ;o)

A flourescent light might flicker more.

You have a problem somewhere. Probably a loose or resistive connection somewhere. Can even be a weak and fried breaker. I can run my 830 off my 15 amp plug under the table here, and I have NO dimming of the lights. I can run it AND my SB-200 amp at 500-600w and still have very little to any dimming of the lights. I'd find the problem as resistance means heat is building up and frying something probably. First thing is to check the breakers, and tighten the wires to the connectors very tightly. Half the time, loose wires are the problem. Next, check the wiring to the 15 amp box. Check that all terminals are tight and clean. Make sure the receptical itself is clean and not fried. Black carbon crud from overheating causes resistance. If it still does it, you may have a fried breaker or maybe even bad or undersized wire. Aluminum house wire is junk and causes these type of problems all the time. You can't use that junk in Houston any more. It's against city code. Hopefully, you don't have that. Copper wire rarely causes problems unless it's overloaded.That circuit is flaky to be dimming that much. I never dim lights here no matter what I run. Of course my big amp is on 240v...:) MK

Any idea how they did that? I once came onto a set of those tank
circuits from a salvaged 600L at a hamfest, and was tempted to buy them,
but wasn't sure about their function and couldn't tell anything about
them from viewing them. They were potted. I always wondered how they'd
broadband them without resistive loading and dropping the efficiency
and/or the Q too much. Looks like another compromise, or maybe too much
of a tradeoff.

It welds 2 pieces of metal together using some magnisium
powder. You have this unit that encloses the 2 metals to
be bonded together and you pour this powder in and light it.

2644. Can anyone identify who made this old vertical antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-25 05:07:14 UTC
From: bechtel@completebbs.com
Message-ID: <822636e0.0111242107.33915c94@posting.google.com>
Source record: 154097

A friend just gave me a trapless vertical antenna he has had since about 1967. If any of you kind folks could help me identify the manufacturer, I might be able to obtain information about obtaining or constructing some needed parts (especially a loading coil). The antenna is identified only as Model 40-0104WX -915-. Instructions (which do not indicate the manufacturer) state that "The Model 40-0104WX is a trapless vertical which is manually tuned to any band, 10 thru 80 meters, by a simple adjustment of the feed point on the base inductor."

Thanks!

Not only that but if the wind gusts up, any small changes in the
spacing of the elements can have large effects on the SWR. In some
cases, it could jump all over the place. Say 40 m on one that also has
80 legs.
>
> Save yourself some time, and wire, just use one dipole, feed it with ladder
> line and use a tuner.

Thats what I'd do if I were using ladder line and a tuner. If he uses
coax and no tuner, what he wants to do will work, but spacing the legs
apart at right angles would work much better and have little to any
interaction. If I did stack the legs close together, I'd use stiff
supports to hold the ends tight. Coffee can lids will never work with
any kind of halfway thick wire, and the tension of getting all the
legs tight. Too flimsy I'd think. I'd use at least a piece of 1x4
strip or a tube of PVC with stacked holes or something as the end
supports. Myself, I just run the legs off to the most convenenient
place. Usually trees. The farther apart the better. And having the
legs in a horizontal V won't hurt much either as long as the angle is
larger than 90 degrees apart. MK

I have a 600L I bought used years ago. Several of the broadband output networks were blown, having arced internally. I managed to repair one or two, but gave up on the 80 meter one, which was more complex. They're a strange combination of multiple coupled windings wound in several layers on a ceramic form, all potted into a hard material. (There's one for each band.) I'm pretty sure the mutual capacitance between the layers plays a part in the overall operation. There's no explicit resistance involved, and the unit is reasonably efficient -- around 50% or so. If I were still interested in working on it, I'd do as an earlier poster recommended, and look up the now-expired patents for an explanation.

Hi,

Thanks to all of the good feedback, I have selected 9913 coax since I have to run my feedline partly through my apartment. However, I need to get it through an opening that is not large enough to fit the 9913.

I have some RG8X and intended to use it to bridge the 9913 on the inside and the outside ensuring that the cable is well sealed on both sides. Only issue is am I defeating the shielding of th 9913 by doing this?

The run of the 8x will be under 1 foot.

Keith

A broadband tank circuit is the antithis of what you find in an amplifier.
Tank circuits are high Q = narrow band, but you can add presets to cover the
bands in steps. Moving in frequency requires retunning to put the impedance
back where it belongs.

OK, let's stick with the mono band dipole idea.. Would it help or hurt if I were to use say 4 wires set to 80 meters and spaced them apart with pvs pipe?? I've been told the wires would radiate off each other and make it act like you have a giant copper pipe in the air for your elements.. I guess I'm trying to get the most gain from a dipole that's possible.. I could take 6" pieces of OVC and join them in the center with like a + section, then drill holes near the ends and feed the wired thru.. The pvc supports would be to keep the wires separate from each other.. Has anyone ever run something like this thru an antenna analysis program? I'd love to see the results over a 1 wire dipole..

Any thoughts??

Paul,
Sounds like your describing a 'cage' dipole. The spaced, multiple
wires do increase the antenna's usable bandwidth, but I'm afraid that 6"
isn't near enough. More like 4 feet, or more, before it makes any
appreciable difference on 80 meters. 6" would be fine for 10 meters,
though.
'Doc

It seems RG-8X takes a bad rap because of some of the cheap grade
products out there. Good RG-8X is good cable.
I would be hesitant to have two splices (impedance lumps) a foot apart
if you plan on any VHF work. That can easily throw a resonant 'lump'
into the feedline that may be a problem. Is it so much further to the
shack from the entry point that you wouldn't want to use RG-8X straight
thru?

I've always heard that you can get somewhat wider bandwidth doing
something like that but I dont know how significant it would be.
It won't increase gain or anything like that. A good dipole has 2.1dbi
gain...you can't make it any better but your method may improve overall
efficiency across the band.

What you are describing is called a cage dipole which increases bandwidth
but does not appreciably alter the gain. You can read about such in the
ARRL Antenna Book.

2667. short dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-25 13:59:57 UTC
From: new general <jerryaa@prodigy.net>
Message-ID: <xP6M7.1224$zR1.232309934@newssvr17.news.prodigy.com>
Source record: 154020

Is there such a thing as a "top hat" for a short dipole? If such a thing is practical? How do I figure top hat lengths, etc. I have seen a formula for a short (less than 1/4 wave for vertical). Is it the same formula? I am considering a 1/4 wave 40 m dipole.

2668. Re: Can't use 8 ft ground rods, now what?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-25 14:04:02 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <9tr12kegb1@uranium.btinternet.com>
Source record: 154025

If, for example, the transmitter is in a bedroom and an end-fed antenna is in use, and there's a longish strap, or several different straps, to the nearest true ground at ground-floor level, that's fine, there's not a lot to worry about.

The ground strap is just the vertical section of an inverted-L antenna which is being fed part way along its length. The radiation resistance and pattern of such an antenna does not depend on the feedpoint position. Feedpoint position affects only the feedpoint impedance and the tuner settings.

If everything in the shack is well-bonded to the top end of the ground strap so that all in the shack is at the same RF potential with respect to ground then the likelihood of RF burns on the lips from the microphone is no greater than in any other shack.

Message-ID: <dy7M7.254661$5A3.96150741@news1.rdc2.pa.home.com>
Source record: 154022

Think of a half-wave dipole as 2 quarter-wave antennas (e.g. verticals) placed end-to-end. The same things you do to shorten a vertical can be done to the 2 sides of a dipole. Common shortening approaches are series inductance (loading coils) or capacitance at the ends (top hats). The overall length of a half-wave dipole is twice the height of a quarter-wave vertical, as it's simply 2 quarter wave elements fed at the center. Yes, the same formulas apply.

==========
You have reminded me. I recall such a peculiar event - when the key was down the shack (bedroom) ceiling light slightly dimmed. There is only one way in which the light can get dimmer and that is for the power-line volts to fall. Light output from an ordinary hot-filament bulb is proportional to the 4th power of the supply voltage and so the human eye can detect quite small fluctuations in the supply.

There must have been some defect in the house wiring, such as the ceiling light being incorrectly connected to the same power circuit on which the transmitter (200 watts) was plugged into. Or the Tx power socket was incorrectly wired to the lighting circuit. Normally, of course, lights and power sockets should have completely different circuits right back to the incoming power meter where they each have their own fuses. I never did get to understand the matter. We moved to another town before the house burned down. ;o)

2674. Tune a duplexer or use another antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-25 15:06:03 UTC
From: jkelleyus@home.com
Message-ID: <c651acdc.0111250706.4f0a4781@posting.google.com>
Source record: 154026

Hi All,

I'm a engineer for a small manufacturing operation that has been trying to breath some life into the company's two way radio system. This system was orginally set up by a ham that worked for us and retired (now unavailable to help due to health problems).

Anyhow, we had a very old base/portable configuration until the last year or so. I've replaced all of the older rock portables with synth MT1000's and HT600's that seem to work great... thanks to all of your help.

This company also ran a repeater at one time, but through the last 5-7 years it went into disuse and has disappeared. I have, with suggestions from the group, successfully modified 2 Radius 25 watt mobiles to use as a new repeater base system, along with a CES-RM20 plus controller. I have one antenna and was planning on using a Phelps-Dodge/Celwave mobile duplexer model 635-509 D6A. These radios are in the VHF 151.xxx - range and the old repeater was on 151.xxx / 153.xxx.

The repeater's use is merely to extend HT range thoughout our plant complex of 9+ acres which includes a bunch of conveyors, equipment and the like. While the portables do well, they don't provide end-to-end coverage.

I don't have a lot of budget on this project so I've kinda pieced things together as an interesting challenge. However, the equipment necessary in tuning this duplexer is not available to me.

So, my question is this... do I find someone to tune this duplexer or try and install a second antenna with a small vertical separation (say 5')? The base antenna is not tower mounted but affixed to a central roof location on a short mast. What's more cost effective for my purpose? I'm not looking to utilize the radios for miles and miles... just a good clear signal from property line to property line.

Any help would be greatly appreciated... Thanks,

John

P.S. I've got some of the older rocks left (HT-500's and Expos) that I might consider trading for tuning help. I know they're worth more than a simple tune job (probably (-:) but maybe we could work something out on that or another antenna if that's the way to go. I know a couple of the Expos and at least one of the -500's was working when taken out of service with fairly new bats installed. I think one of

the -500's even has a speaker mic. I also have a 6 bay gang charger
for the Expo's... I think it's still around!!!

Questions/comments.

Does your current FCC station license allow a repeater on the frequencies mentioned? Is the Radius radio "type accepted" as a Base Station in the service that you'd operate under (Part 90?)?

I don't have a Celwave catalog at home, but if the 636 is the small 6 helical (1" x1") type that I *think* it is, it only offers about 80 dB isolation at 5 mHz separation and is totally unusable at the 2 mHz spacing you suggest. Depending on the characteristics of the TX and RX that you propose to use, you need a minimum of 90 dB isolation (noise and carrier), maybe more.

Source record: 154030

Hi All!
I am new on 50 MHz, about one month activity. Now my antenna is Cushcraft AR-6. I'd like to build an antenna with more gain. I think what 6 ele quad is better choice for me, but still can not find any practical construction. Please let me know where I can get complete info concerning home brew 50 MHz quads.

It is easy to try the vertical separation option, and you can easily build another antenna, it's not difficult to make a simple vertical dipole or ground plane. But depending on the equipment you yave you may need a lot more than 5 feet of vertical separation. But you can always try it and see how it works out. My guess is that using modern wideband synthesized gear with wide open transmitter power amps and receiver front ends you'll have more receiver overload than you can deal with.

Tuning a duplexer requires specialized equipment and techniques.

Yes. Last year or so there was an article in Worldradio Magazine about a
short dipole using spiralwound heavy aluminum ground wire (available at
Radio Shack) as the end loading elements, which would provide both
inductive and capacitive laoding on a very short antenna. Looked very
interesting but I had no need of one so I havent tried it.

Pardon the blank post.

Have you measured the voltage drop
when you go key down? It doesn't take a lot of voltage variation
to cause a visible change in lamp brilliance. Part of your problem
maybe due to sharing the same branch for lighting and operating the
station.

It certainly won't perform anywhere near a rhombic, and you are right it
is similiar to a B&W unit.

You should go to the duplexer manufacturer first to determine whether the duplexer is suited for the split you are using. You will need at least 80 dB if you are running more than 20 watts and a solid-state transmitter. Also, the Radius mobiles, unlike Mitreks or Micors, lack the helical preselectors used in the older Motorola mobiles and offer little isolation from signals a few MHz away. Right off the bat you are giving yourself a disadvantage by using receivers with broadband frontends--you are losing isolation and have a very hot receiver to boot. Most mobile duplexers are spec'ed for a 5-MHz split, and if you insist on using that sort of duplexer you will need to use that wide a frequency separation. .

You need a lot of vertical seperation to achieve the isolation needed for repeater service, I'd guess 50 feet to start, when using a Micor or similar base. One other option for separate antennas is splitting the duplexer, and using one leg for addition isolation on the RX and TX sides; you can pick another 20 to 30 dB of isolation with a split duplexer and two vertical antennas with moderate separation. Horizontal separation is more stringent, since the vertical separation places each antenna in the other's so-called "cone of silence".

Personally, I'd sell the mobiles, and go on eBay and buy a good Micor or Mitrek (MSR2000) repeater/base for the 80 or 100 bucks they've been going for, and do it right. Ditto for the duplexer. The older commerical stuff is selling for dirt cheap prices.

Tuning the duplexer is easy, you need a receiver that will cover both frequencies, two 6-dB pads, a signal generator and a means to monitor the limiter voltage. Those are simple notch duplexers, and you simply tune each side for maximum attenuation of the notch frequency (RX on the TX side, TX on the RX side.)

When it was named, bands were referred to in terms of their wavelength -- not frequency. Then again, there was this old book '200 Meters and Up' ... I guess it all depends on your point of view.

BamBam (?)

The only way that an antenna, which is a completely passive device, can provide "gain" is to modify it basic pattern, in the manner of squeezing a balloon. If you get twice the signal in one direction - a 3 db "gain" - then the signal in one or more other directions has to be reduced by the same 3 db. An antenna is NOT an amplifier - it is not a power converter: DC input to RF output.

As CAM and others have posted, using multiple elements connected together and fed in common can provide a broader SWR bandwidth but no power will be radiated than from a single wire at the same resonant frequency.

To make that a little clearer, if you use a multi-wire "cage" antenna cut for 3.8 MHz, you will get a certain level of performance. You would get the same level of performance from a single wire dipole also cut for 3.8 Mhz. Now, if you QSY to 3.5 MHz, the cage antenna will work better than the wire dipole cut for 3.8 Mhz, but no better than a single wire antenna cut for 3.5 MHz.

In antennas, as in life, "there ain't no free lunch! A dipole is a dipole and no variation of it is going to provide "gain" as such. Some antennas provide more signal in some directions, but that is all.

Hello Brent,
I would suggest you take a look at the W9INN MPD-5C dipole. It has resonance on 10-15-20-40-80m and comes in either 78ft length or 87 ft length. The longer version has a bit more bandwidth on the lower bands. It is rated for 1500w pep and comes assembled and pre-tuned to your specs. I have had the 78ft version up at 54ft for over 5 years with no trouble and 299 DXCC countries to boot....it works well.

The official W9INN page is at the web site listed below. There are illustrations, real-world measured bandwidth data and contact info.

A capacitance-end-loaded dipole is just two 1/4-wave-resonant
top-hatted verticals connected back-to-back. The ground connection
loss is, of course, zero.

For design details, using any number of radial rods for a top hat,
download program TOPHAT1 from website below. Download in a few
seconds, not zipped up, run immediately.

belden 9913 is 50 ohm coax with low loss, if the short piece of coax you want to splice in is also 50 ohm impedence, the only difference will be the extra loss of the short piece of coax which is more lossy than 9913, and the loss through the connectors, unless you solder everything. There should be no impedence mismatch.

No, my watch tells me that's OQ2 .. not OS2 .. chuckle ..

BTW! I actually HAVE a CW card on 40 meters from OQ2GU in 1954!

And no, I thought that it counted for that SPECIAL one too, but
I was wrong! When I submitted my first submission for DXCC with
300 on 40M, 300 on CW, which I DID get awarded, that was one of
the ones I used! Turns out that there are TWO sides to that river!
If your card is from OQ you CAN get credit, but for which side of
the revolutionary war over there, it depends on which side of the
river the operation was from!

I actually 'had' more than 300 on 40CW, but that was one of the
few I lost credit for over technical difficulties!

An OS2?

You know .. the other half of WIN-NT that hasn't had to be rebooted in 7
years now for any op system crash... out at W5WQN at the remote site..

except for the time when the REA power crew couldn't get power
back to it for more than 24 hours. The APC Rack mount couldn't
hold it for longer than that ..

Giggle ..

That's why nobody knows what it is!

I guess I really oughta show it this way, sigh ... since it's only half
an operating system anyway!

--> Sleep well; OS/2's still awake! ;)

Don't know the frequency in question but 50 ohm BNC connectors don't
cause much of an impedance bump up to 460 MHz.

When you put top hats on a horizontal dipole, they are normally referred
to as "end hats" and they work well. End hats for short dipoles are akin
to folding the ends. End hat designs are somewhat unpredictable
in the real world and most hams just cut and try.

I'm sorry to hear the problems with TT. Owner Gerald Williamson has always treated me super, though I haven't seen or talked with him in several years. He always took time to chat.

His son, Matt, who may be running it now, does NOT have his father's "bedside manner." He can be abrupt and sound like he doesn't much care, but he has always taken good care of my orders and me in person. I'm sure employees will tend to reflect the attitude of management. It is a very tough business with little-to-no profit and hams tend to be some of the tightest, most difficult buyers in retailing. They probably run short-handed and over-worked. Unfortunately, the overall impression is that they would rather be somewhere else, doing something else... If I were in their shoes, that would probably be true for me. A long time ago, I spent 15 years in that business. I would have to be starving to do it again. My hat is off to those in the business who are able to retain an interested, caring attitude.

I wasn't referring to mismatch but I guess thats what an impedance lump
would best be described as. I work in cable tv and even with >30db
return loss connectors and cable you'll see that 'odd' section between a
pair of splices on any sweep or TDR and its freq will be dependent on
the length of the odd part. So if its for VHF/UHF use, it would at
least be advisable to make sure the jumper section length (* its VF)
won't be 'resonant' at any desirable freq.

Hi Andy,

I am pretty sure from my memory of twenty odd years ago that you are Bill Swiffins son!! Bill was one of my technicians when I was at Ferranti Microwave! I often wonder if any of the lads from those days are still about.
As regards capacitors in gamma matches you do not need them! You just alter the length of the element to reflect the required reactance! Saves all that fiddling about and all the weather problems of capacitors. You will notice on the standard single band 144 MHz halo that there is just a tap, with no capacitor...It takes more time to develop, but is much much better from a production point of view!

Hi Paul
There is nothing wrong with your idea of a multi band dipole. The only thing I see is the coffee lids are not strong enough. I have built 2 of these types of antennas, and i am currently in the process of building a third for a friend. The first one I built was for 80/40/20/10, and 15 would work on the 40 meter element with a little use of a tuner in the shack. It is true that they are tricky to tune when building them.But the first one I had up never changed it's SWR even if the wind was blowing it around.And the last one dosen't change either. When I built the last one for myself I addressed some of the constuction that I didn't like in the first one. Even though the first one was up for over a year and a half, with no trouble at all, and was still working great when I took it down. As for my , at this point, prefered constuction, I used #12 insulated solid copper wire,1/2 inch sched 40 PVC conduit to make spreaders, spaced the wires 3 inches, and used a 1to1 current balun at the feed point. I made all of the elements intentionally too long, stung it out about 10 ft off the groung for rough tunning. I tuned the longest wire (80 meter) first, then went to the next longest and so on untill I had all of them close to what I wanted. Then raise it up to its normal location. After checking the SWR curve on each band, I lowered it back down and made adjustments to the two lowest bands the rechecked them all up at height. Then lower it again and adjusted the higher bands, and rechecked all again. I have found that the longer element have more affect on the shorter ones when pruning them, so I get the two longest ones set first the set the higher bands. As you can see, it does take some effort to tune, but once its done it works GREAT! I had a 80 meter doublet(130ft dipole fed with 450 ohm ladder line to a tuner) up at the same time as my first parallel dipole, and the parallel dipole was lower ,but out recieved the doublet most of the time, and I didn't need to do any tuning on the parallel dipole. Just change bands in the radio.I know some will dissagree, but that was my obsevation here.I do agree a 130 ft doublet is a good antenna. But other than the work involved in tuning the elements in the presence of the others, I really like the perfomance and, with one coaxial feed line and no tuners or anything else between the antenna and rig but coax,I like the simplicity of the multi-band parallel dipole.. Let me know if I can be of any help if you decide to try one.
Good luck ! 73 Rob K4MAU

From the get go in our house had cable; now DirecTV. We have jacks in the master bed room and the family room right above each other. I had seen a cable in the attic. I assumed the cable in the attic went from the upstairs bedroom to the family room (a straight run). Purchased an antenna from RS to avoid paying the $6 monthly local channel DTV charge. Went up into the attic to find two cables! Both are coax: one has a jack on the end and one just has a bare wire. The transformer supplied with the antenna takes a coax and then splits into two flat wire connectors to the antenna. I think what I need is a 2 into 1 coax connector to hook up with the antenna transformer. But what about the bare wire? Is it hard to put a jack on the end of a coax cable?? Does a 2 into 1 exist (and is this what I need)? Any and all help would be most appreciated. Steve Ignots

I'm interested in buying this antenna for 40m thru 10m operation. But, I can't find a picture or physical description of it.

Can it be hung from just two supports or must each wire have a separate support so that their ends are separated from their "neighbors?"

What sort of feedline do they recommend?

If you have one, what do you think of it?

Thanks, Pete KA0TZK

Putting the connector on is the easy part. What you want preferably is
two coaxes straight to the main TV/rcvr location...one from the dish,
one from the attic-mounted antenna. Your Direct TV receiver should have
separate inputs for antenna and dish. From there you can route to
different rooms. There's all sorts of esoteric combinations that you
can scheme up but be aware that the Direct TV line carries not only RF
but a DC voltage as well and whatever splitter/combiner gadgets you use
must be able to pass the DC voltage.
All of the items are commonly available. Figure out what you want to do
and go to Radio Shack...this is where their employees really shine in
being helpful and you should get change from a ten. The bare-wire thing
was somebody's kluge...ignore it.

George, W5YR wrote:
"A dipole is a dipole and no variation of it is going to provide "gain" as such. Some antennas provide more signal in some directions, but that is all."

Very true, but most antenna people would call concentration in a particular direction "antenna gain". To the receiver it produces the same signal increase as a transmitter power boost.

Ignoring the broadband goal, some of the wire used to make cage elements could be instead used to lengthen single-wire elements to slightly more than 1/2-wave total length. This gives antenna gain. The price paid is loss of bandwidth over which the dipole has relatively constant response which came from the cage. Then, there is another price which is a narrower beam width for the dipole because as George said the gain in one direction comes from a loss in another direction. Also, there is a third price in stretching element lengths only slightly. The antenna is now not resonant, so external arrangements must likely be made to reconcile the antenna with its feedline. But, you were going to use a tuner anyway to resonate the cage antenna system as you hopped around the band.

Best regards, Richard Harrison, KB5WZI

>like you have a giant copper pipe in the air for your elements..

That's about right. A 4 wire cage with the wires 3 feet apart will cover the
entire 80/75 meter band with less than 2:1 SWR. (A typical single wire 80 meter
dipole will only cover about 200-250 kHz with less than 2:1 SWR). In addition,
the length of the cage dipole is less than that of a single wire dipole cut for
the same center frequency.

If you have 2 trees 125 feet apart and want to work the entire band, it can do
a good job.

> I guess I'm

>keep the wires separate from each other.. Has anyone ever run something like
>this thru an antenna analysis program? I'd love to see the results over a 1
>wire dipole..

The cage offers NO significant gain over a single-wire half-wave dipole. The
only reason for the cage complexity is to get more bandwidth.

You can get a few dB gain from a center-fed dipole by making it 1.28
wavelengths long. Doing so will require some sort of matching system because
the feedpoint impedance will not be directly compatible with coax.
>
>Any thoughts??

For dipole analysis, download Reg Edwards' DIPOLE1 program and play with it for
a while. It's free and easy to use.

Irv, VE6BP wroyte:
"I think I`ll stick to my butane torch and silver solder."

That`s what I did, though I knew better! I thought, as many tight turns as I took around that rod, it`s almost a giant wire-wrap connection and it`s soldered too. When and if lightning hits, the ground cable can`t fall away and it will continue doing its job. It is secured just above the wrap. To be safe I could put a clamp over the joint, but I think I won`t bother as long as inspectors don`t bother me. The rod is like a belt with suspenders as I have a clamped connection to underground metallic piping, too. Ever try to solder a pipe filled with water? NEC in the U.S. doesn`t require the rod but the electric power company does. They haven`t refused service without the approved clamp. I believe HL&P, the power company, accepts CadWeld too, though I don`t see it in their service standards.

Best regards, Richard Harrison, KB5WZI

Never is an improbable occasion rate.

Several investigators report transmitter output impedance measurements of nearly 50 ohms.

There is no law or electrical inhibition barring a 50-ohm output impedance.

Reg has occasionally said something like: ---plates, collectors, and drains have high impedances, therefore transmitters are high-impedance sources.

Device impedance doesn`t dictate output impedance. The devices when switched-on can have a low voltage drop that when divided by the current they are conducting is a quotient much less than 50 ohms. There are tubes and semiconductors that pass amperes with just a few volts (or less) dropped across the device.

Output impedance is determined by the percentage of the time the output terminals are not exposed to the switched-on, near short-circuited, output device. Transmitter output stages are not Class-A amplifiers.

Walt has it right!

Best regards, Richard Harrison, KB5WZI

if you put the quad at the top of the tower and the vertical above it the vertical should be atleast 5-6 feet above the top of the quad also check uinto what would happen if you pass a metal mast thru a quad most quads dont like it at all unless they are end mounted you may need to use a fiberglass mast to cut down interaction
good luck

You could use about anything. I think originally they just used a
normal tapped airdux type coil. I like roller coils on those myself.
Makes it easy to dial up any frequency. You could make a homemade coil
and tap it for different bands. What it orignally amounted to was a
"home use" bugcatcher, with the coil at the base. You tapped the coil
with a clip to change bands. MK

Thanks for the identification! If Gotham's been out of business for
many years, does that mean I'm out of luck as far as finding a loading
coil or specs on how to make one? Is the antenna even worth holding
on to, if only for nostalgia's sake?

The Gotham advertised a "special B&W loading coil", so any decent coil stock by B&W or Airdux would do. You could probably make a better one using copper tubing. As far as nostalgic value, unless you had the original coil I doubt if it would be of any real value other than as a possible element for a homebrew vertical. At one time it was my dream to own a Gotham, but I could not afford the $18.95 (US) even though the Canadian dollar was worth more than the US buck in those days. The $18.95 was for the 160 meter version -- the 40 meter version was only $14.95!

Time for story of old radios: WW2 CW radios (behind-the-lines) used a multiple tap on the primary of PS to accommodate for wide variations in line voltages and then, when keyed, the transmitter switched between the transmitter and a load. The result was that one could not find the transmitter just by looking for an area where the lights flickered. Saved lives. 73 Mac N8TT

P.S. An Engineer's house where lights flicker because of the switching of any appliance would be a source of considerable ammusement.

...was a Feng Shui reference.

http://www.technoscout.com/general/product/product.asp?product=125&Prod_Name
=Xium_Antenna&site=85420
(cut 'n' paste if necessary)

Anyway, I could hardly make my way through this ad(?) / article(?) for a
small receiving antenna.

"Fully automatic 360-degree tuning. The core of the antenna has multiple,
90-degree angled plates. This spilateral design creates an all-directional
antenna that receives almost any analog or digital signal from any radio
frequency broadcast tower."

Huh?

Anyway, the most disturbing thing was that this was linked from ABCnews.com
without any on-page indication that it miiiiight be an ad.

Hi Rich,

I notice you don't say exactly 50 ohms.

And why 50-ohms ? Why not 75 ohms for the same amplifier ?

What value did you get when you measured yours ?

Or what value did you obtain when you calculated it ?

==========
Take a look at page 573, "Communication Engineering", W.L.Everitt,
1937, McGraw-Hill.

With reference to a triode, Equation 41a states -

The load resistance for maximum power output is -

RL = Pi * Rp * (1 - Cos(A)) / (A -Sin(A)*Cos(A)) / (Mu + 1);

where Pi = 3.142, Rp is the tube's internal plate resistance, Mu is
the tube's amplification factor, and A is 1/2 the tube's operating
angle in radians which may be anything from Class A to extreme
Class C conditions.

Everitt takes the trouble to state: "RL is usually low in
comparison with the plate impedance".
==========

If you design your own PA linear with its output transformer to
'match' to 50 ohms (which I'm sure you can do) you don't need to
know what the internal resistance is. If someone gave it to you,
you wouldn't know what to do with it.

If you're not careful you'll be re-kindling for the umpteenth time
the great "that elusive conjugate match" debate. ;o)

;o)

It takes a bunch of electrical engineers to come up with naming conventions
that are recripricals (sp?) of each other. <:-))

Is this the kind of thing you can get out of the Eznec program? If
so perhaps I should get a copy.

If the standard L/2 dipole comes out at about 10ohms, how
about using a folded dipole to give a 4X transformation
to about 40 to match into 50ohm coax (if you don't tell
about the missing 10ohms I won't either!)

> trying to get the most gain from a dipole that's possible..

You really don't want gain unless you want to point in a certain
direction. For 80m, most of your average operation will be in all
directions.
What you want is efficiency. A normal dipole is about as efficient as
you can get as long as it's high enough off the ground to avoid excess
ground losses. For general purpose use on 80m, in all directions, my
#1 preferred antenna is the turnstile. Which are crossed dipoles. I've
never seen any other type of antenna do a better overall job, and yes,
I've always been able to notice a difference from a single dipole even
though the turnstile is omnidirectional if fed with a 90 degree
phasing line between the elements. But I noticed the same increase
even if I fed in phase and had a dipole pattern. Hard to explain
really on paper, but they work. Does well on 40m also. I once used a
dual 80/40 turnstile fed with one coax. Had 8 legs equally spaced.
Worked real well. If you only have room for a single wire I'd stick
with a normal coax fed dipole as high as you can get it. Will work
about as well as anything else out there. Using a cage dipole would
just complicate things as you have an impedance transformation for one
thing. A normal dipole is already a good match to coax. You don't want
to get away from that if you want max performance on 80m with a
dipole. After you get though matching up the 300-450??? ohm feedpoint
of a cage dipole back to the 50 ohms your radio wents to see, you will
end up with less radiated signal than a regular old coax fed dipole.:(
About the only way to avoid it would be to use a Cecil type no tuner
measured ladder line feed. Even then I don't think it would radiate
any better than a coax fed dipole. "or turnstile which is also a low Z
feed like a dipole". In this case, simple really is the best I think.

Pete,

I have a 6BTV, and you can forget that "no radials" thing. That only applies if you have perfect ground, which virtually no one does.

There's always a debate about whether a few long ones or many short ones are better, but for me, 2 radials cut for each band worked OK. Not great, but OK.

Is this just a section of telescopijg aluminum tubing? Sounds like one of
the Gotham verticals.
They used a large section of coil stock at the base. It was up to the
owner to determine how much coil to use on each band and where to tap it
for 50 Ohms- requires a decent ground radial system of course.

Broadcasters have listeners in many directions at once, they hope. The same may be true for hams in a net or hams hoping for subsequent conversations when the current conversation breaks. Often though, it`s a one-on-one conversation, and only one azimuth counts. Beam antennas give power gain in this instance. A single dipole gives a couple of db gain over an isotropic.

In the case of a single dipole versus a turnstile, the gain is 3 db for the single dipole because you are not wasting half your power perpendicular to the desired direction.

Not having a switch to disconnect the dipole you are not using in a crossed pair is convenient, but when you are not broadcasting, it costs power in the desired direction.

Gain on transmit is also gain on receive. More important may be the rejection of noise from undesired directions.

Best regards, Richard Harrison, KB5WZI

Reg is right. We`ve been there and done that.

Everitt is one of my heroes and i`m sure Reg correctly quoted him. We are agreed that "RL is usually low in comparison with plate impedance". My intrepretation would be: "Plate impedance" is Mu divided by Transconductance in Everitt`s statement.

Politics and religion must both be involved in the topic of generator impedance. As Reg said, "---you don`t need to know what the internal resistance is". Yes. Not many commercial transmitters are loaded to maximum watts out anyway.

Had a similar problem of soil depth out at the cottage .
Basically using more ground rods is the only way to go , providing they are in connected a few feet apart and in parallel. What you end up electrically is three .5 ohm resistors (the ground rod) in parallel making a very low resistance to earth.

Hi Andy,

A folded dipole would be an answer, but I don't see it in the ad
copy's picture of the antenna (and neither does the text describe it).
You could also test this hypothesis with eznec.

What is described is a T Gamma Match, which also eludes my scrutiny of
the picture offered. That is, unless it is buried as discrete
components in the small junction block that the feed line attaches to.

How does a SB200 'make up the difference' of lost receive signal
microvolts? Most antennas are used for both transmitting and receiving
-thus, turning up the power won't help you hear any better, just feed
the QRM tub.

A little basic review of most any antenna guide will help you understand
the need for a good RF GROUND.

I recently bought an MFJ-9406 6m SSB radio and an MFJ 3 element 6m yagi. When I tried out the radio, the SWR's were off the scale. I tried re-making the balun a couple times and even improved the "pigtail" coax connector that connected to it.

Finally I decided to switch the coax off of another antenna I had. I knew that coax worked without any problems. I hooked it up, keyed up the radio and BOOM the SWR problem was fixed! But that's not the suprising part. I hooked the other coax up to the other antenna and that antenna's working fine with the coax that didn't work properly on the 6m antenna.... any ideas why this might happen?

Unfortunatly, it's Radio Shack coax, RG-8/U.

The Cobwebb ad describes a Tee gamma match, I guess it must be made up
of twin feed or something similar, like yourself I studied the picture
carefully
but couldn't work out how Steve had done it!

I'll try it out on the eznec program, thanks for bringing my attention to
that
I'll get a copy. I'll also try out a couple of examples in real wire, this
looks
like becoming a fun project.

Cheers
andy

Hi Ted,

First, you will need a ground to work against or tuning will be dicey.

A Folded design could be accomplished through using the shield of the
20M drive line. It is grounded to the tower at the top, held off from
the tower by 3" stand-offs and fed against ground, at the bottom. The
capacitors required range to a high of 600 pF. Consult
"The Amateur Radio Vertical Antenna Handbook," Capt. Paul Lee.
Or press me for more details if this sound attractive.

2756. Carolina Cyclone Antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-26 18:12:31 UTC
From: Jerry Oxendine <joxendi@bellsouth.net>
Message-ID: <ZCvM7.47452$q36.3271557@e3500-atl2.usenetserver.com>
Source record: 153960

Are you in the market for a screwdriver-type antenna, but the prices seem a bit steep? Then I would like to tell you about the Carolina Cyclone line of multi-band mobile HF antennas. Consider
that, while hamsticks are cheap, by the time one acquires enough to work all HF bands, he will have spent enough to buy a Carolina Cyclone! Plus the fact that the screwdriver antennas will sig-
nificantly outperform a hamstick. Not only that, with the Carolina Cyclone, you get ONE antenna
that does all bands 80-10- meters + 6 meters (in most cases), and you don't have to worry about
storing those whips, or getting out of the car to change antennas.

About construction: The Carolina Cyclone's internal parts are made of extremely tough black Nylon (Nylok) which is UV resistant, is extremely durable, and almost impossible to break. The
choice of this material was made after much discussion with the supplier who manufactures these
parts for me. This material makes the use of powers of up to 1500 watts SSB possible. Some people prefer Phenolic or Delrin. However, these materials cost far more without giving any signi-
ficant increase in durability or power handling. And, if a customer specifies Delrin, for example, he
can certainly have it, as well as powder coating. It raises the costs with little benefit in performance or reliability.

The Carolina Cyclone I is a full 2" dia. and is wound with #14 wire at 8 TPI for excellent form factor and performance. It is nominally rated at 800 watts SSB. At a cost of only $240 shipped
to the lower 48 states, it is an excellent choice for a active mobileer who wishes to get the most from his mobile rig.

The Carolina Cyclone II is for the extra serious mobileer who wants the absolute maximum from
his mobile and an significant increase in power output. It will handle full legal limit with ease. Construction is the same as the Cyclone I using a full 3" coil form. This antenna has also been used
as a fixed station vertical with good results. The price for this model is $340 including shipping to
lower 48 states. Compare and SAVE Both antennas are fully warranted for 12 months against failure.

Thanks for reading and 73

It could be, you have an intermittant short or loose connection in your bad/good coax. Move it around, shake it, and see if it goes "in and out."

Other than that, my only comment on RS coax, I've compared the braid on RS coax to the braid on Belden coax, and the RS braid is much, much, much more thinly woven. Probably not the best of stuff to be using at vhf frequencies.

Try using an RF choke at the antenna.....several turns (6-12" loops) of the coax....RF may be feeding back via the shield. I fixed a 2M problem this way, as well as a similar problem with my 6M J Pole and an older tube amp.

Andy,
There could be several reasons, probably the most
likely is some kind of 'mechanical' fault. Maybe a
bad solder connection as others have said, or (?).
I wouldn't blame the Radio Shack RG-8/u, though.
If you take a close look, and evaluate it fairly, it's
probably as good, if not better, than quite a few of
the other 'brands' of coax out there. Radio Shack
doesn't make their own coax. They do like a lot of
other retailors do, just have thier name put on it.
If you took the name off of it, I doubt if you could
tell it from 'Beldon' or any of the others.

Gee, if it were ~600mH, it could be pretty interesting, but unless it
has a ferrite core, I come up with something closer to 800uH.

Still, not too bad for over 200 feet of 14ga silver-plated wire.

Cheers,
Tom

Pete,
Contrary to the 'no-radial' claims made by a lot
of the vertical antenna makers, they all benifit from
having radials under them. Any antenna, vertical or
horizontally polarized 'works' better with a good
ground 'under' them.
How many radials? As many as possible, or until
you get to the "to hell with it" point. How long should
the radials be? About as long as the antenna, maybe a
little longer. Longer doesn't 'hurt', but it doesn't
help all that much either.

Source record: 153967

Warning - many of you may consider this a "dumb question"...but here goes...

I moved into a house with an large aerial antenna on the roof. A RG-59 coax cable comes down from roof on the back of the house, and then comes back into the house to a jack on my living room wall. Pretty standard, I presume.

Th problem is that When I connect my TV to the antenna jack (RG-6 cable from coax wall jack to coax antenna-in jack on TV), I get VHF channels with no problem, but UHF channel reception is extremely poor. While troubleshooting this problem, I discovered that when I touch the center conductor of the TV cable to the sleeve conductor on the wall jack, UHF reception improves to near-perfect picture quality (better than VHF, in fact); however, VHF reception is poor.

So, for some reason, the VHF signal is coming in primarily on the core conductor, while the UHF signal is coming in strongest on the sleeve conductor. The TV, I'm presuming is expecting both signals on the core (it's a Sony WEGA). Does anyone have any suggestions for "mixing" the signals to the core lead on the cable? One experiment I tried was to place a piece of aluminum foil inside the cable jack end, touching both the core conductor and the sleeve, but this produced no result. Any other strategies to try?

Thanks,

Chris Woodfield

I've had similar results with the Radio Shack cable. The threaded part of
the PL259, when tightened as tight as possible, will not clamp down on the
ground part of the cable. The cable will still spin and flop around under it
making for an intermittent connection.

RADIO SHACK sells some of the most marginal quality trash available. If
the quality dropped just a smidge from where it is, you could take the stuff
off
the shelf and throw it directly into their dumpster, and it would save both
them
and us a great deal of trouble.

Chris,
It sounds like 'normal' UHF reception on a non-UHF
antenna. What happens is that the 'shield' of the
antenna feedline is acting sort of like a 'long wire' on
UHF, which would give you a 'better' picture than the
'nonresonant' VHF antenna would. The 'cure' is to use
an antenna that is designed to receive both VHF and UHF
signals.

Well, the "bad" coax is working fine on my CB antenna now.. took the 100' RG-8
I had hooked up to the CB antenna and hooked it up to the 6m antenna and the 6m
antenna works fine now, as does the CB antenna.. guess I won't worry about it
unless either one starts acting up.. :)

Sir,

My memory is that the coil was about 3" in diameter, 5 or so inches long
and about 4 or 5 tpi. This should give you a starting point.

> Hi Andy and Richard and all!

Yes you have it correct Andy. I was playing about with a dipole whilst developing my end coupled 5 band VK2ABQ type beam antenna and I bent it into a square and noticed that the feed Z was 12.5 ohms. I thought, "Hey if I made it a folded dipole the Z would be 50 ohms." I added another wire spaced about 2 inches from it and after a bit of pruning sure enough it was!! It was left like this for the evening and when I was having my sked with VK and ZL that night I still got 20 over nine reports so I thought that I might have the basis of a very small but efficient antenna!!

Note that the shorts between the 2 half wave lengths of wire need to be at the high Z ends of the elements if the velocity factor of the transmission

line formed by the 2 half wave lengths is 1, as it is with air dielectric. This then forms the standard looking folded dipole that you see used on V/UHF yagis etc.

If you use twin for the elements then the shorts between the elements need to be at the velocity factor out from the centre. If you calculate the tapping points then adjust the lengths for the resonant frequency afterwards, the required change of tapping point will be quite small. Lots of work with shorting pins before you solder anything, especially if you are doing it on 5 bands!

If you are trying to do a 4:1 transformation the tapping points are exactly the same distance out from the centre for a folded dipole as they are for a double gamma tee match, but the sums are much easier!!

I did try using wires spaced about 3 inches apart as velocity factor 1 folded dipoles, but no good in the wind with flutter de-tuning! Also not very strong and also hard to assemble. I found that they needed to be individually resonated and it was very fiddly. It looked more like a real cobweb though!

Another way is to use a 4:1 balun, or should that be a 1:4 balun!! The problem then is it is hard to get it flat across 1 octave and you need an enormous ferrite core if you are going to run a few kilowatts! They do!!!

One bit of advice that I would give to anybody playing with antennas, if you make a set of triangular "coils" with 6 inch sides for your FET dip meter, you can couple into half wave wires without affecting the resonance of them. Get your resonance correct first then do your matching and finally trim for resonance again. I made mine exactly the same inductance as the original coils so the calibration of the FET dip meter still held.

I have a one turn triangular coil with five turn 1 inch diameter coils at the two other corners and I squeezed the coils till I got the inductance value correct. I have a smaller "coil" with 4 inch sides for the higher frequencies and a large 6 inch triangular coil with 7 turns for the lower bands. All made from 14 SWG wire and the ends soldered to a bit of pcb and bent so that they plug straight into the same place as the normal coils.

Very useful for checking guy resonances and co-ax length resonances (to make sure no large currents on the outer due to inadvertently having a half wave of co-ax feed length). I put a choke balun on the CobWebb so that people can use any length of co-ax on them but I had never had any problem with RF on the outer of co-ax in all the years that I have been making co-ax fed dipoles.

The first time I had a problem was when I was developing the CobWebb and I was using a half wavelength of co-ax so that I could measure the antenna Z from a distance without the equipment affecting the antenna. Talk about RF feedback problems, the rig hooted like mad! I hear that lots of people have problems like this with RF in the shack, a choke balun will cure it but I think that most of the problems occur because people deliberately make the co-ax a multiple of half waves long!!

Anyway enough waffle from me, 73 and have fun. Note. You should develop antennas in the summer!! I always swore that I would never work on antennas in the winter after developing a wide band antenna whilst at Marconi Space and Defence, in the snow! I felt really sorry for the lads making all the adjustments whilst I was doing all the measurements in the lab!!!!!!

2777. Re: UHF/VHF reception problem - how to combine UHF and VHF on a single conductor?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-26 22:03:53 UTC
From: Scott McClements <yetbbwa@grove.iup.edu>
Message-ID: <3C02BC49.1B70805@grove.iup.edu>
Source record: 153977

Is your antenna designed for UHF reception? As Doc' 'stated', if you hook up the outter portion of the coax shield, you are basically hooking a really long wire to the antenna jack that acts as a antenna - not as effective as a antenna designed for UHF reception. So, your coax is acting as the antenna - not your rooftop mounted aerial.

Your problem is more than likely the coax cable loss at UHF frequencies. Even a short length (~50 foot) of coax cable loses most of the signal the antennas picks up before it makes it to your TV receiver. You must use a high quality coax along with a *antenna* mounted pre-amplifier. Radio Shack sells these "mast mounted" pre-amps. This will boost the signal up right at the antenna so that even though some signal is lost as it travels down the coax to your TV, your TV receiver will still get a strong signal. The higher the channel on UHF, the more pronounced the cable loss is.

Scott McClements.

Don't overlook the Cable TV distribution cable option. Even though it is 75 ohms, it is cheap (often free) and certainly low loss. If you are worried about matching, do a Google search of postings on this NG for the past couple of years for plenty of discussions. Discussion result summary: Don't sweat it.

When using those on 80m, the turnstile seemed to show gain in all
directions.
If I had a dipole N/S , and then added another dipole E/W to make a
turnstile, usually even the people broadside to the N/S dipole show an
increase. The people E/W show a large increase. What always seemed to
happen was backwards from what you say would happen. I always seemed
to show a good 3-5 db increase on the S meter switching to the
turnstile. No matter what direction they were in. Thats why I said it
didn't make any sense on paper. I'm guessing it may be due to a
compressing or squashing of the H plane. Also you have 3 ways of
feeding if you have a phasing line and switches. You could feed purely
omnidirectional, or you can feed them to have a dipole like pattern in
two directions. On 80m, it didn't really seem to matter which way you
fed them, I would still see the increase in performance. So I got to
the point I'd just feed them straight like parallel dipoles. Every
time I've switched from a dipole to a turnstile, I could see the
difference just in receive s meter readings. It would always seem to
jump about 5 db on the S meters I used. "Using the upper scale of the
S meters, usually in over S 9 range." What I should do is set up a
turnstile with switchable feedlines so I can switch the different
directions from the shack. "omni, E/W, N/S, " That would let me do
more exact tests as I could A/B fast.
Every time I switched from dipoles to turnstiles on 80m, it's like I
add 3 db to my signal. Every time I switched back to a dipole from a
turnstile, it's like I lost 3 db. I guess I've done this about 4 times
in the last 15 years or so. The last time a couple of years ago. I'm
presently just on a normal dipole, as I am using the two extra legs
for 160m or 20m, depending on where I stick insulators. It's on 20m
right now for SSTV... I can switch to an 80 turnstile pretty fast.
Maybe I should do some better tests of that antenna. BTW, a guy I know
that experimented with egg beaters "crossed loops" saw the same effect
comparing crossed loops to a single loop. I'll quote his comments:
K5HDQ said,

""First we made one loop. Next we put up a sample dipole and a
relative
field strength meter at a distance of 140 feet. With 100 watts of
transmitter output we set the meter to about 75% scale.

With loop #2 in place we found that 50 watts would give us
the same reading on the field strength meter. Thats 3 db
gain over the single loop, 5 db gain over a 1/2 wave dipole.

To look at the radiation pattern we rotated the antenna through 360
degrees and logged the meter reading at regular intervals. To our
surprise the readings were very nearly the same for the 360 degrees.

The only way we could figure to see a gain and still be
omni-directional would
be compression of the H plane, which means a lower angle of maximum
radiation.""unquote...

He's the one who gave me the idea of the H plane compression maybe
being the cause.:

So anyway, pretty interesting the way they act when crossed. "Both
dipoles and loops" . I want to do further tests on that to see if it's
a fluke or real. The turnstile is the best GP 80m antenna I've ever
used so far, in any direction. It's a definite letdown to go back to a
normal dipole. I wonder what an egg beater would do...I don't have
room to find out on 80m. MK

80m for me is almost never one on one. I talk with large groups
usually in all directions. I would never want a real directive antenna
on 80m unless I were working dx. Same for 40m usually. MK

Heck no. The beam on top will help as a top hat of sorts and make it
closer to a 1/4 wave. Should work well. But like Richard said, you
will need a few radials. MK

2783. Re: CCD ANTENNA

Fred,
Check in one of the ARRL's antenna compendium books. I
rememebr seeing a 'basic' program for determining wire segment
lengths and cap values.
The CCD is a very nice antenna and does almost everything
claimed for it. If made for the lowest band you will be using,
it'll work on any band above that, and very well. It isn't
'shape' or height critical either.
There are three things that might be considered the 'down-
side' of using a CCD antenna. You have to use a tuner, the
antenna is very long, and it takes considerable time and effort
to make one (not as cheap as a dipole). If you don't mind
using a tuner and have the room to put one up, all that you
really need is patence.
'Doc

Generally, verticals need more radials when ground mounted than elevated.
If this is a vertical dipole design, this may be the reason for radials when
elevated. I'd start with four radials. Use multiconductor TV rotator
cable, cut one of the lines on each radial to quarter wave on 10, one for
15, one for 20m and start from there. This will give you four radials, each
one having an "element" for each band.

---------- etc.

Good luck, and Good DX.

Howdy, I have never posted on a newsgroup, and know very little about amatuer radio, but perhaps someone here can point me in the right direction. Let me explain my situation. I work for a small construction firm in Dallas TX. We have for years stayed in communication with our field employees via 800 mhz. 2-way radios. we have had to switch service providers recently, due to the fact they stopped servicing the frequency our radios operate on. Now our new provider is doing the same thing to us, but now there does not appear to be anybody in town that we can use our radios with, due to they have all sold thier frequencies to Nex-Tel. Now we are apparently going to have to buy all new equipment that works in the 450 mhz. range. I am looking for info on A. Is this legal for a big corporation to make my equipment obsolete. B.To educate myself on what choices of new equipment would be best for my company. Does any body know where I can find such info on the web.

RG-59 is also pretty lossy at UHF, so whatever signal you had at the start, is likely down 3-10 dB by the other end of the pipe, depending on length.

Mark Keith, NM5K wrote:
"When using these on 80m, the turnstile seemed to show gain in all directions."

The tortoise outran the hare but only because the hare wasn`t performing properly.

Turnstile antennas are omni antennas, and are used by some VHF and UHF broadcasters because omnidirectionality is what a broadcaster needs.

A dipole antenna is bi-directional, used for gain and interference rejection where omni-directionality is not necessary. The 3 db gain advantage of the simple dipole over crossed dipoles as used in the turnstile is not speculation. This fact is documented and published in respected journals.

Without some enhancement over the basic models of dipoles and crossed dipoles, when these are all placed at the same heights in the same sites, the 3-db advantage in the best direction of the simple dipole should be measurable every time. (Testimonials and advertising claims to the contrary notwithstanding.)

Squashing of the H-Plane must be advertising talk. The magnetic field can be concentrated as seen in ferrite-cored receiving loop-sticks. This is the product of core permeability. There is no such mechanism involved in a turnstile.

The items reported in scientific and engineering journals have more credibility than something in the National Inquirer. In the serious journals, items are exposed to criticism by competent reviewers. If behavior contrary to the experience of many seasoned observers occurs, the author should have an explanation or maybe a reasonable speculation. If he doesn`t have an explanation, it`s very possible there was a fault in measurement, reporting, or the basis of the experiment was flawed.

Egg beaters, I assume are loops around a stick. They may be relatives of the folded-dipole turnstile. Except for impedance, folded antennas behave as do their open-end relatives. Egg beaters aside, adding a second similar directional antenna to equally share a fixed amount of power with the first antenna, and to send that power in a direction not covered by the first antenna, logically cuts power in the first antenna by half.

You might note that if you were marginally in ground wave contact with a station perpendicular to the wire in your horizontal dipole, and if that station were using a vertical antenna, adding another dipole to your station with its end pointed at the distant vertical antenna would

likely improve communications. I`ll leave it to the reader to explain why.

Best regards, Richard Harrison, KB5WZI

I think that if you model this antenna you will find out that it is not worth
the effort-the model used in AO actually has LESS gain than athe same length
wire w/o the capacitors.
To quote K6STI regarding this "the easiest way to increase the gain of a 1
wavelength wire is to extend the length 28% forming an Extended Double Zepp."

It will radiate and you'll be able to make some short-range regional contacts. It will not be a DX world-beater since at that height there is going to be little low angle radiation. Still with that said one can still be quite satisfied working the stations you will be able to hear....

Making the best of your situation can be a very rewarding Ham Radio experience. I am limited here from having a tower and beam..yet with simple dipoles I still have 299 DXCC countries and looking for more! I can tell you each one of those gives me greater satisfaction than if I was on a tall hill with a stacked array of mono-banders and legal limit power....I am determined to make "Honor Roll on a Dipole!"

Hang in there and accept the challenge..it makes the results much sweeter.....

Message-ID: <U1EM7.63788$Lo5.8089498@e3500-atl1.usenetserver.com>
Source record: 153999

Well.

Doc, it may seem so to you, but if you were able to compare the two up close you would quickly see there IS quite a difference. For example, most of the "average" screwdrivers are 1 1/2" diameter and PVC. They are wound with #16 wire at 10 turns per inch. Mine are a FULL 2" dia.
and are wound with #14 wire at 8 TPI. The result is higher efficiency and a better signal. There is
no PVC anywhere in mine. Try putting a few hundred watts on PVC and see how long it takes to
make yourself a rather expensive slinky toy as the PVC shrinks right out from under the wire! The
material is a tough, resilient Nylon (black), and is much cheaper than Delrin and Phenolic. The
Delrin is more brittle, the phenolic is aggravating to turn on a lathe because it comes off the machine
in long, messy strings of waste which makes for more cleanup time in addition to the already expensive price. It is kind of funny, but I've had some lengthy arguments with "engineers" who just
insist that these antennas "must" be made of Delrin or else. Fine. I'll make it out of Delrin, but the
cost will increase significantly. You can't tell an "engineer" anything--I mean, they've got that piece
of paper that signifies they know everything about everything, right? If you don't have a degree, then
you don't know sh**! Never mind that you have built antennas for five years and the material chosen is because at least half that time was spent experimenting, researching, and trying different
materials. Never mind that the owner of the Plastics Company is a Master Machinist and has 15
years experience in building and forming plastic parts for a huge variety of industries such as textiles,
trucking (2 Freightliner plants are in this county), and bearing companies....to name a few.

The object was and is to build an excellent antenna at a cost that most hams can afford. Whether
anyone believes me or not, I have achieved that goal. I have shipped antennas all over the USA.
As to volume, I don't really WANT to sell more than a couple per month. I am retired, and I only
do this as a hobby and a small supplement to my income. If I don't sell any antennas, it doesn't
really bother me--I make just as much sitting on my butt as I did when I was working. It is just

something to keep me busy. But I DO know this: having built as many antennas as I have, I know what works, and the Carolina Cyclones do a bangup job getting thru the QRN, and they WILL outperform the "average" screwdriver. I've already tested them, and I have had customers to tell me that they compared theirs with friends' DK3 type "average" screwdriver. Their buddies' DK3 type, "skinny" little units got their tails kicked! One such is Robert Lewis, Daugherty Rd, China Grove, NC who compared his to a friends' DK3 (I can't remember his call right off).

Finally, if you could see a Carolina Cyclone close up, you would easily recognize that it is built more ruggedly. For example, many of those "average" screwdrivers have those thin, Butyl coil covers that last about a year before the owner is looking for a replacement. The stuff cracks, splits and disintegrates in the WX. I use Lexan tubing which is 1/8" wall. It resists weather for years and doesn't discolor like the cheap Butyl. Incidentally, I keep some of those covers around, so if anyone is looking for a replacement cover for your DK3, they are $15.00 ea shipped Conus.
There are a number of things that sets the Carolina Cyclones apart such as the drive assembly.
Many of the "average" PVC screwdrivers use a T-nut or a threaded wood insert (brass) just screwed up into a PVC bottom under the loading coil. Sooner or later, this will work loose or strip out immobilizing the coil. My coils have a 1/2" pipe threaded hole on the bottom into which a 1/2 X 1/8" bushing blank is screwed and locked with another screw. A 1/4" x 20 TPI X 1/2" turnbuckle nut is firmly secured in a drilled hole at the bottom of the bushing with JB Weld. It is almost impossible to break or strip this out. It would take some major "wreck" or incident to mess up this method. That's all I'm gonna tell about how they are put together. But everything I did to, IMHO, improve the basic screwdriver came about because of something I ran into previously or discovered was just not up to snuff. If no one recognizes these improvements, well, that's OK. I will still build them and even give them to my friends or to Civil Air Patrol members I know. If I never make a dime, I still enjoy making them for the satisfaction of seeing something I built work like it's supposed to. Ah, before you ask, the answer is no. I ain't makin' free antennas unless I've known you for about 15 years! LOL!

Thanks, Roy. I expect the blown networks were the result of working into too much of a mismatch. That would seem to be a problem with any fixed output network just as it is in solid state transcievers.

Hi folks!

Since the weather is strangely warm for the time of year, I have decided to tackle a project that I
have put off for a long time; that of putting up a 160 meter antenna. I don't have quite enough
room for a full length dipole, but I determined that I have about 200 feet from the front of my lot
to the rear-and I guess I should count myself lucky to have that. By winding 25 feet of wire onto
2" forms, I can insert these loading coils in the 2 sides and shorten the antenna enough to fit the existing space. I think it will work fairly, but I don't expect truly exemplary performance. If you
were doing this, where would you insert these coils; at/near the feedpoint, in the center of the wires, or out near the ends?

It will be very good for "local" contacts out to a few hundred
miles. It will suck for DX. It is pretty much an NVIS antenna.

Hi, Jerry...give the boys an education!

FWIW, I've seen quite a few of Jerry's antennas, played with a few and all the owners that I know rave about them. Only problem I have is how to mount it! That would be the ONLY reason I'd use an ATAS instead of Jerry's unit. If you have a full sized vehicle (instead of the plastic thing I drive...and a company car to boot...no holes allowed) Jerry's antenna is the cat's meow. I just can't figure out how to attach it to these new plastic cars.

No association with Jerry except to admire the workmanship, and I do wish I could mount one on my company Grand Prix for mobile use instead of the HamStick (as I'm limited to 6M at present).

Radio Works doesn't make any big claims for the CW80 Special on 80 and
they are correct. It 'gets you on 80' and that's about it. If you are
using a rig with a built in autotuner, generally speaking, it will not
tune the CW80 Special on 80. I have only experience with the Icom IC-746
but Radio Works says the same thing. I'm not a big 80 meter man and have
never used anythijng else on 80 so I don't have a direct comparison to
make. I'm in the Pacific Northwest and guys in 6-land say my signal is
'weak but readable' if that means anything.

On the other hand, it works as claimed on all the other bands. I've used
it a lot on 20 and 17 and get good reports. I have also used it on 6 with
fairly good results even though the antenna is not really designed for
that use.

I hope that helps you some. I'm happy with it because I wanted to be on
80 and didn't have the room for a full length CW80 or a dipole. It works
fine in my book. The CW 40 is 'tweeked' for 40 so you might get better
results on 40 with it. I guess that's the choice you have to make-
half-assed 80 meter antenna with good 40 performance or no 80 meter
performance and excellent 40 meter performance.

Dale,
Having had two of the CCD antennas I have to disagree
with part of your post. If you read the literature about
CCD's you will see that there is little or no 'gain' over
a 1/2 wave dipole. But 'gain' wasn't the purpose to start
with. Frequency mobility, highth independancy, and being
'shape' insensitivity are it's 'positive' characteristics.
I do have an antenna modeling program and like to use
it, but so far haven't modeled a CCD. I'll have to try
that. One thing to remember about the 'modeling' programs
is that they don't tell all the 'story', and the 'operator'
has to be able to tell when the results are a bit out of
the 'ball-park'...

Accuracy in the spacing of the coil is paramount. I've now built several of them (2m to 40m) with mixed results. They work especially well in tandem, like a double coiled dipole. Tuning is a bit tricky.

Jerry,
I guess the 'screw driver' technology has progressed some since I got mine. I know from having learned the hard way that PVC isn't the coil core material of choice. My 'screw driver' didn't exactly turn into an "L" shape, but it certainly couldn't be used for a straight edge either (LOL)! But then, it uses a broad-banded torroidal input matching scheme, which is a very poor way of doing things compared to others.
Most of the 'screw driver' antennas I've seen in this area have been at least 3" in diameter. Of course they weren't made for how they 'looked', but for how they worked. Larger coil diameter is a desirable feature, especially on the lower frequencies, as you know.
The only reason to have a 'screw driver' antenna is ease of changing frequency, you don't have to stop, get out, change the tap, etc. Other than that, they really have nothing 'over' most of the other mobile antennas. I've also found that mounting them can be a real problem on some vehicles.
As I said to start with, I'm not 'bad mouthing' your antenna, not having used one I can't honestly comment on it's worth. I'm just making general comments about the 'screw driver' antennas that I have seen or had experience with.

Now let's look at this logically: Radio Shack = Radi
Coax = ax
Therefore, Radio Shack Coax = Radiax!

Actually, I once found some RG-58 that was worse than the Radio Shack
equivalent - braid is too liberal a word to describe their
lattice-work of copper wire around the center conductor.

Seriously, with the power level you have with the MFJ-9406 and 100
feet of cable you might be reading a better SWR than you have due to
loss on the return: which on RG-8 at 50 MHz is, I believe, around 3dB
- or half of the power. You really may wish to consider upgrading
your coax: try to keep in mind that you have spent some $$ on a radio,

perhaps some more $$ on an amplifier, more $$ for an antenna &
mounting hardware so spend a little extra $ (not much compared to your
'system' cost) for some good coax and instead of losing half your
signal (transmit and receive) bring that number down as low as
reasonably possible.

Howard

Source record: 154015

Greetings,

Try a search on the ARRL web-site. You should get
some (ahem) practical advise. This could include links to some
"horror stories" of those who've had to do battle with local pols.
and their ignorant constituents.

Perhaps a key question (that maybe I missed your answer
too) would be: What is the distance to nearby structures? Fer instance,
if you own a 1/4 acre lot than it's a certainty that anything over 50+ feet,
even if errected in the center of your property, *will* be sure to hit partly
outside your prop. line if it topples. In the face of local hassle ANYTHING
that is built can be considered a "structure".In other words, if it's even
remotely possible that your tower might topple onto a fence or patio even,
this might be used by small minds to block or obstruct the issuance of blding
permits.
Looking at the 1/3 acre lots on my street, a 200ft. tower would never
be approved without a costly fight. There's simply too much it can topple on
from houses to power lines for any Inspector or Town Council to ever grant a
variance on it. If you know someone who has done that then tell him congrats,
but don't expect to match his sheer good luck.

It's not all doom and gloom, but don't kid yourself either. a Tower IS
a structure, it will freak out at least some of your neighbors, the reaction of
all local govt's will be suspicious and perhaps negative. People will think you
are placing them at risk for lightening strikes, or cancer, or (God Forbid) RFI
to their sunday TV game watching. There is no limit to ignorance when it
comes to Ham Radio. There really are cases out there where local govt's
tried to pass laws (quickly killed) banning Ham radio or Ham Towers and such.
(I'm not kidding.). Join ARRL, avail yourself of their Tower legal aid packet
-- yes you need will need it. Believe nothing that local goverment says without
legal advise. Don't fool yourself into thinking you can do the legal work. Do
some simple math and footwork to find out a few facts about what you can
afford and local knowledge regarding Tower hassles, etc. and then hire an
attourney and do it right. You don't wanta sink 10-20K or more into a tower and
then find out you'll need to " move it over 3 more feet" to satisfy some loony
local ordinance. I don't have a tower, but was shocked when I researched
a little into the subject.

Hope this helps,

Andrew

Not in my case. The normal dipole was performing properly. Did just

I realize that. I've already said twice it didn't make sense on paper.
Or modeling for that matter. Don't you think haven't tried modeling
these? Of course I have. I did it a long time ago. Turnstiles are also
bi directional when not fed 90 degrees out of phase. And some of the
times I used these, I didn't have them 90 degrees out of phase. In
fact, as I said before, the increase I seemed to see, didn't really
seem to come from 90 degree "omni" phasing as I had the same good
results with them in phase or out. The guy that tested the eggbeaters
on 10m said he got the best results signal wise with 180 degree
phasing. He tried 1/4,1/8 and 1/2.
>

> the contrary notwithstanding.)

Should be. It seemed to do just that when he tested the crossed loops
against a dipole and a single loop. He also did a test where is
converted a single 2m loop to an eggbeater and noted the same thing to
local stations in the area. But he didn't mention how much the
increase was on 2m. I assume it was about the same as he saw on 10m.

But in his 10m tests I've already noted, he did. And the FS meter was 140 ft away. Not real far, but thats a few waves on 10m. Seems that should be far enough way that the FS meter should be fairly accurate for the tests he did adjusting the power levels in the large amounts he varied them." From 100w to 50w" or 3 db worth. How do you explain his results? He did the test you are referring to. In the real world, with real antennas on 10m. He may have made an error, but you will have to take that up with him. I wasn't there.

>
> Squashing of the H-Plane must be advertising talk.

No, that was just his guess. He's not in the antenna biz...He's a ham in N.Texas that just happened to try one and test one with 3 different degrees of phasing. The antenna project was featured in a computer antenna calculator program he wrote.

>
> The items reported in scientific and engineering journals have more
> credibility than something in the National Inquirer.

I don't read the National Enquirer. And I don't believe everything I see in a book. Plenty of books have been proven wrong or incomplete. I don't think there is much info on this particular subject anyway. Most people that run turnstiles use them for VHF SAT work, or commercial, and assume 90 degree phasing is the way to go. It is being they want a near perfect omni pattern.

In the serious
> journals, items are exposed to criticism by competent reviewers. If

I'm just comparing the overall performance of a dipole against a turnstile on 80m and noting the results. I've changed back and forth 4 or 5 times. It's quite possible it's a fluke in comparing the two due to changing cdx,etc, but there is no question the turnstile was an excellent 80m antenna. The best I've ever used, and I used to live on 80m every single night nearly. I have tried nearly everything to get the maximum signal I can on that band. Dipoles, loops , dipoles with reflectors, ad nausium till the cows come home. I'm talking to the point of anal retention in getting every last drop. The turnstile always seemed to outperform my normal dipoles. I'm not explaining why, I'm just telling you what the results were. Every time I switch to one, everyone says I have a better signal than before. And a usually a noticable increase at that. It's happened every single time. Every single time I switch back to a dipole, I lose performance. " In my case it's usually to the west out towards Midland, El Paso, etc.". My dipole is N/S pretty much. A more accurate test would be done by running twin dipoles with twin feedlines, and being able to run

separate, or both , in phase or out of phase and do all that from here in the shack on the fly. That would settle it once and for all. For me anyway.. I've never been able to A/B them at the same time, because the original dipole used makes up half of the turnstile that is used later. I am one seasoned observer. There are very few other observers of any type that have tested these antennas in this manner, so I have no other results to compare to. In other words, no one else has tested this to say if I'm wrong or right that I know of. If there are any others than the one other person I know that ran one in LA, where are they? Are you one of them? Do you run 80m and have compared these also? I'm open to any conflicting views. So far I have none. The only views I've heard are the people that say my turnstile is the best out of what I run.

>
> Egg beaters, I assume are loops around a stick.

Just crossed loops. Doesn't have to be a stick.

>
> You might note that if you were marginally in ground wave contact with a

> station were using a vertical antenna, adding another dipole to your
> station with its end pointed at the distant vertical antenna would
> likely improve communications. I`ll leave it to the reader to explain
> why.

This was to many stations over a long period of time. 95% of them out of town. No ground wave. Most all the others were using horizontal antennas of whatever type. No verticals. This was mainly NVIS stuff. Texas, and the surrounding states, with a few stations on both coasts. This was also tested 4 or 5 times over a period of 15 years. I also knew a guy in New Orleans that tried one, being I had such good results. He had the same good results, and said he seemed to notice about the same apparent increase in overall performance. At this time, I can't really tell with accuracy how they compare without an A/B test, but I can say 100%, the turnstile is without any doubt the best antenna I've used on 80m for general purpose use. Many tout horizontal loops and dipoles with reflectors under them. I found the turnstile better than either one of those here. I tried a horizontal loop at 40 ft, and it wasn't any better than my dipole at 40 ft. So it's not just from having twice the amount of wire in the air, although I don't think that hurts.
I think I'll test this before I make my change back to the 160m mode for the winter. I'll have to dig up equal feedlines, etc to set it up. I'd like to know the answer myself. Doesn't make sense at all to me on paper or with modeling. If you run a turnstile with the elements in phase, you get a dipole pattern with less gain than a dipole. "about 1.2 dbi" if you run at 90 degrees out of phase, the pattern is omni with -.9 dbi gain on the azimuth plot. The vertical plots are about the same on both with less than a db difference. So obviously modeling

is not telling me anything really useful in finding out the reason for the supposed increase. According to it, it shouldn't exist. And it didn't make sense to him either when he tested the eggbeaters. Thats why he's guessing on what causes the effect. I just know they seem to work. How well, I'll know later...After that, I guess I'll be the only one in the country that will know for sure, unless someone else chimes in with their test results. Well, wait, if my results match HDQ's, I guess he'll know also...That'll make two that I'll know of. Except his were loops instead of dipoles. The amount of people I know personally that have tried turnstiles on 80m, I can count on one hand. One thing to note: if the H plane was squashed, you would think the dx sigs would pick up, and a slight reduction of overhead NVIS sigs. This didn't seem to happen. I saw no reduction of strength close in. If anything stronger. It's something I've been curious about for a long time. Even if I end up finding the increase of performance is real, I bet that wouldn't buy me a cup of java at the enquirer... :(MK

I did the same thing a couple of years ago. Made two versions of
different lengths to test. Overall, I recommend at a least 1/2 of the
way out. The best spot is probably closer to almost 3/4 the way out,
but once you are 1/2 out, I think you will be ok. About the same as a
bugcatcher. It's a toss because the farther out, the more turns
needed. You could use Reg's vertload program and find the "best" spot
fairly accuratly with a bit of testing. I since ditched the loaded
antennas and went with a Z dipole full length. I may also put up
another inv L later. It's about that 160m time of year... MK

I didn't like the ones I tried at all. A normal dipole ate it for
lunch on 80m. And the windom we used was higher than the dipole. And I
did A/B that test with a switch...No grey area on that one... MK

Hi Jerry,

I'm afraid loading coils are not just a way of dumping wire which cannot be stretched out into a straight line.

The inductance of a loading coil to bring an antenna to resonance, and hence the length of wire on it, depends on its position along the antenna.

It is a fact that if the 25 feet of wire is made into a small coil and put right on the end of the antenna it will not have slightest affect on anything.

Anyway, for the sake of 25 feet its certainly not worth the bother of inserting coils. Performance-wise neither you nor the fellow at the receiving end will notice the slightest difference. You will just have somewhat different tuner settings. You could ease your consciemce by calling it a double-size G5RV.

But if you insist on it being resonant and you are unable to get the full length out into a straight line, all you have to do is extend the last 12.5 feet of wire down towards the ground at each end.

Good DX !

It will work very well. I would think most amateur 80m dipoles are
only 30 feet high anyway. They just don't brag about it. ;o)

The ARRL Antenna Book has the answers you seek. The further out toward the ends the better for efficiency, but the coil inductance value needs to be increased. They have charts in the book that allow you to figure out where to put a coil with a given reactance to achieve an overall length. You will still end up pruning the outer ends of the dipole for fine tuning, so leave them a bit long...I find it easier to cut wire off until resonance is found rather than twisting wire and soldering to add to the length...plus it looks neater! The downside to this is that you will need to know the inductance of the coils to plug in the reactance value into their charts. You can do it with an LCR meter if you have one or by putting a capacitor of known value across the coil and use a dip meter and some calculation to figure the coil inductance. I built a 1/2 size 160M antenna (total length was about 133 feet, or about the same as a halfwave dipole for 80M) this way by putting coils of 75 uH at the halfway point in each leg. It worked fair, but my antenna was only at 10 feet and I noticed it only had a 2:1 SWR range of about 12 KHz. Not sure if that was due to ground proximity or because of the coils...I would guess the coils were the factor as usually the proximity to the ground seems to make an antenna more broadband due to ground losses or some other wierd phenomena...at least that's how it seems to work in MY neighborhood! :)

Which is exactly what the manufacturer said would happen. The CW80
Special is a shortened version of the CW80.

I would be interested in people's experiences comparing a CW80 (full
length) to a dipole or other antennas.

> Where would you insert these coils; at/near the feedpoint,
> in the center of the wires, or out near the ends?

Hi Jerry,
I have not tested that in practice yet. According to theory, given the length of the whole antenna: the coils at the feedpoint have the smallest inductance and the antenna's efficiency is the smallest, too. Moving the coils towards the ends, the coils must have a bigger inductance and the antenna's efficiency increases (provided the losses in the coils are kept low). Neverteless, placing the coils very near or directly at the ends is no good: the coils require some capacitive loading. If it misses, the antenna gives strange and bad results.

CAM wrote:
"Sorry for the typo - should have been ~ 600uH."

My Lightning Coil Calculator never made a mistake, but I have. Thought I should check with a calculation.

Terman says: uhy = F (nn) d
F comes from a chart that uses l/d = 0.011
n = 77
d = 5.25

x4 uhy =1370
(half the coil was used again so the results are x4)

1370 is close enough to 1400 from the Lightning Coil Calculator. Obviously, I have flawed data as Terman and ARRL agree on the determination. Some error is expected because the F-factor is non-linear, but my error is excessive.

Will modeling experience do? :-) EZNEC indicates that the CW80
has more gain off the ends than a dipole and less gain broadside.
It has considerably more vertically polarized low-angle radiation
than a dipole. Thus, for close-in broadside work, the dipole will
be superior. At relatively low heights, the CW80 should outperform
the dipole for DX. A $20 conventional Windom or inverted-L will
do the same thing.

http://www,arrl.org/

Look at the ARRL Antenna book for published schematics
and tuner theory. The ARRL antenna compendiums are
also good sources of ideas and plans.

The tougher issue is usually parts, especially rotary inductors
and big air-variable capacitors.

Have fun!

Look inside the one you borrowed. You'll find two variable capacitors in series in the line between your radio and antenna; with one end of a coil attached between them and the other end grounded. That's the scheme for a basic "T" network ... called "T" for obvious reasons. That's all the high-$$ units are - they just have specially built parts.

Radio >-----)(------)(------> antenna
C
ground

Many scrounge the cap's from old radio receivers (remove every other "plate" to improve voltage handling) then wind their own coils with taps going to a switch for convenience or a simple shorting clip-wire for better accuracy. Enjoy! KA3DWW

Mark Keith, NM5K wrote:
"This was mainly NVIS stuff, Texas, and the surrounding states, with a few stations on both coasts."

Mark knows what he`s seen and that includes better performance from a turnstile than from a simple dipole in its best direction. I believe Mark, and think we should use what is found useful regardless of theory. We can find why it works later.

The turnstile seems to work near and far, and one would hope in most azimuths. If so, its gain must come from reduced radiation at very low angles, or at high angles despite the NVIS performance.

Some unknown local condition could explain the success of Mark and other investigators, but if the success can be repeated by many others the turnstile should become very popular at h-f.

Best regards, Richard Harrison, KB5WZI

>I can only put it up that high. How well will it work?

For over 15 years my 80 meter dipole (along with all the rest) was
only at 10 to 12 feet high and I earned my DXCC with no problems.

The major portion of my 160 meter antenna can be reached from the
ground if you can jump up a foot or two.

Now it's (the 80 meter dipole) up around the 18 to 20 foot height and
I don't see much difference after going to all the work to double it's
height.

I have an 80 meter vertical, noisier, but works much better.

I said I`ve made mistakes and I`ve done it again. I read 72 as 77. Recalculating the inductance using 72 turns gives me 1198 uhy, not 1370 uhy. I had the same mistake using the Lightning Coil Calculator, so it would give the same corrected value as the calculation.

Hi Doc,

Having looked into this breed years back, I find it curious that you
would describe it as:
> Frequency mobility, highth independancy, and being
>'shape' insensitivity are it's 'positive' characteristics.
and summarily dismiss gain with:
>CCD's you will see that there is little or no 'gain' over
>a 1/2 wave dipole. But 'gain' wasn't the purpose to start
>with.
This is certainly not found in the literature of CCD's.

In fact, the whole point of the individual elements was to tune for a
specific band (the antenna is specified as being at least one
wavelength long, an obvious reference to tuning and not "frequency
mobility"). Further, the combination of the L of the section and the
C of the cap are tuned at one frequency for the specific effect of
creating a string of current maximas to increase the launched signal's
strength.

As with any massively tuned system, the accumulation of phase errors
from so many elements can debilitate the design and thus the CCD
encounters problems of assembly and application uniformity that is
required before this will work properly.

Check the links toward the bottom of this page: http://www.cebik.com/radio.html
Cebik has several articles on tuner theory and construction.

For parts, Surplus Sales of Nebraska has them,
http://www.surplussales.com/SSIndex.html
but once you start pricing the parts, you may find it's cheaper to just purchase
a pre-built. (You could probably get something cheap on e-Bay.)

Richard,
We must not have read the same article. The antenna's length is a full wave length to obtain enough inductive reactance for the addition of the capacitive reactance of the capacitors to be effective. As to the 'shape' of the CCD, as long as it isn't doubled 'back on it's self', any configuration will work. Same for height, from laying on the ground to as high as you want to put it. This is all from actually using a CCD antenna. Rather than going through all this, I'd suggest looking at the 'Antenna Compendium' series from ARRL, they have a very good article about the CCD antenna. I can't find mine, or I'd give you the volume number and page. Shouldn't be to difficult to find though. There also used to be an outfit in Hawaii that made them commercially (for what it's worth).

Sideband,
Unless your a very good 'scrounger', and happen to
be near supply houses that carry 'old' stuff, it will
probably be cheaper to buy a tuner, and I know it'll
take much less time. In my area, about the only place
to find some 'larger' capacitors is at a hamfest, and
depending on the amount of power you put through it,
and the antenna, your going to need to find some fairly
hefty caps, not to mention a suitable inductor.
Good luck...

A long time ago, I checked the accuracy of the old
"L=(n*r)^2/(9*r+10*l)" formula against some other formulas, including
the L=F*n^2*d one as given in Grover's "Inductance Calculations."
Presumably, the latter one is pretty accurate if the table of F values
has been calculated correctly. Grover should be a good source for
those F values, I think. I came to the conclusion that it (the first
formula above) is close enough for any normal ham work I'd be
doing...worst-case errors for _reallllly_ long coils was around 8
percent as I recall, and for more practical coils, the error was far
less. When I estimated the 800uH, I used the first formula. I just
checked again, against the second one, and came up with about
780uH...plenty close enough for me. I used 144 turns, 16" length,
2.7" radius (assumed a 5.375" form diameter, leading to a slightly
larger mean helix diameter). I didn't correct for the fact that the
pitch changes at one point along the coil; but I did do a sanity
check, calculating it as two separate coils and considering the
probably mutual inductance. So...I'm not sure why your value is
coming out so high...but suspect it's cuz the coupling between the two
halves of the thing you calcualted isn't anything like unity. You'll
come a lot closer, I think, if you just apply the formula (whichever
one you choose) to the whole coil.

Cheers,
Tom

I don't recall where I read it, or why it is supposed to be so, but a loop is supposed to have a lower angle of radiation than a dipole at the same hieght .

My loop runs between existing trees in a triangle shape. It is 30 feet high on two corners, and the third corner is only about 20 feet up. I figure it is about 225 feet around. I have worked Europe on 10 mhz the last two nights. I know I have worked both coasts on 80. I have made contacts out to 1,200 miles on 160.

I agree that building will cost you more than buying.

At the risk of being flamed for reccomending Ebay...

Do THREE searches on ebay in the Ham Radio area. One for tuner, one for coupler, and one for Match.

You will find around 60 devices for sale at any time, with many under $50.

If you do read the Cebik artilces cited earlier you may get interested in Johnson Matchbox. On Ebay the ugly ones go for under $60 and the pretty ones for under $110. I bought three on Ebay for a project, for less than the cost of the components used.

It will work just as well as mine. Ideally, you should put
it several wavelengths above ground - 1000 feet would be nice!
Most of us have to settle for less.

I get really good reports out to about 600 miles. Beyond that,
stations with higher aerials or verticals usually get better
reports than I do.

Mine works really well on 40M and is quite good on the other
HF bands too. I use 600 Ohm balanced feeder.

Something's wrong here.
When I put on a pl-259, it does NOT spin or flop.
I dress the cable end, and tin the braid.
Then I thread the cable into the 259, solder the center conductor to the
pin, and solder the braid to the shell.
I couldn't tell you how many I've done, but it's a large number.
I use the RS silver-teflon connectors. The other ones melt, I don't know why
the make those.

|It will be very good for "local" contacts out to a few hundred
|miles. It will suck for DX. It is pretty much an NVIS antenna.

Not picking on Cecil, this is just a good spot to chime in. Also, I'm not usually a proponent of anecdotal evidence and for sure W8JI's vertical and Beverage farm works better but...

My 80-meter inverted-vee is a bit higher (about 43' at the apex and about 25' at the ends) so maybe my QSOs, through the contest pileups, with 9M6NA (8400 miles) and JT1/K4ZW shouldn't count as DX <g>.

Also, my dipole is fed with 250' of coax, not "ladder line", and we know how bad that is. And the Asian QSOs were off the end of the antenna and there isn't any radiation in that direction either. So theory says you can't make these contacts.

So there can be only one explanation: superior operating skill <G>. Put your antenna up as best as you can and hone your skills. W8JI, W5YU, W7DD, et.al. will work the DX first then you can be next.

> experiences.

It sounds like what you have is a horizontal wire fed at the end with
open-line. At the antenna end, one of the open-line wires connects to
the 414 foot antenna wire, and the other open-line wire goes to
nothing. Correct me if I'm wrong on any of this.

Such an antenna is the classic "end fed Zepp", so named because it was
used on zeppelins 60-70 years ago. In order to work, the antenna wire
MUST be a resonant length. 414 feet is not a resonant length for 80 or
20 meters. The result is a very unbalanced feeder and a
difficult-to-match impedance at the tuner, RF in the shack, losses all
over the place and disappointment.

Most manufactured tuners (including your MFJ) today consist of an
unbalanced matching circuit (the variable capacitors and inductor)
plus a wound-toroid "balun" that can be used for balanced loads. This
system works fine for unbalanced loads and for SOME balanced loads. It
works poorly for balanced loads that are highly reactive or outside
the design impedance of the balun.

Try this simple test: connect the two wires of the open-line together
at the shack, and connect both of them to the UNBALANCED output of the
tuner. Make sure the tuner is grounded and see if you can get a match.
The results should be much better. If so, replace the open-line with a

single wire and you're all set.

In my limited experience, an "inverted L" single wire/tuner combo beats an end-fed Zepp of equivalent length every time.

Hello folks,

I would appreciate if someone out there can help me to identify the
complete
manufacturer's name, location, web site, etc. for the amateur line of
antennas
that are marketed as TSM-1314, TSM-1316, etc.

A web search has yielded two dealers, one in Italy and the other in
Germany, but
nothing more than model number and pricing.

Please reply to my email if you prefer - jas2001@optonline.net

Thanks in advance - Joe, N2QOJ

Hi Richard,

Not sure what you don't understand. The antenna elements are made from twin and there are no Cs so just taps across the twin at the correct points. Am I missing something??

It may all be a fluke of some sort, but it's still interesting the way
they work. The tests the other guy ran with the eggbeater is what gets
me. I ran across that after I had used the turnstiles a while. The
first couple of times I tried one on 80m it always seemed to be a
noticable increase in performance. But I just put it down to a more
omni pattern filling in the gaps and maybe a slight bit of help from
having twice the amount of wire in the air. But then I ran across the
tests that the other guy did with the eggbeaters. That really got me
to thinking.. This is something I'll have to test here to prove to
myself if it's a real effect or not. When you switch from a dipole to
a turnstile. You don't see gain per say in any certain direction. It's
just like you increase the efficency a bit. About like comparing a
twin lead fed antenna with a a tuner, against a coax fed dipole. About
that amount of difference. The noise, signals , all go up about 3-5
db's worth on an average meter. Or seemed to anyway. The only way I'll
know if it's a fluke or not is to run the twin feedlines and be able
to switch on the fly. I could probably try this on 2m to make a easy
way to test on a smaller scale. Also could duplicate the eggbeater
tests the other guy did, and see if they repeat here. MK

The one we tried was a full length 80 meter verion. Not the short one.
The short one would be worse I would think. The problem with the one
we tried wasn't wire length per say I don't think, it was excess loss
in the feedline with all that ladder line to coax with a choke mess. I
threw up a quick coax fed dipole and used a switch to compare and the
dipole won by "S units" No matter what direction or distance. And the
dipole was about 10 ft lower. It was a radio works windom, but the
"regular" 80m version. I'm not up on all their models..This was tested
at a past field day about 3 or 4 years ago.. It did seem ok on 40m.
Nothing special, but usuable. I guess it was even usable on 80m if you
don't mind a weaker than normal signal. MK

> KA9CAR

Mainly due to height above ground in WL. On 80m the horizontal loop
has almost the same takoff angles as a dipole. Maybe about 1 S unit
more going straight up, so actually, the dipole should have the
capability of a slightly lower angle on that band if both are the same
height. Not much difference really. As you go up freq the ant will be
higher off the ground in WL, and it starts showing lower angles. But
so will the dipole also. The loops do seem to make good multi band
antennas. MK

2857. OPP Monitoring the OPP,, How to get rid of squawking???

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-28 00:18:12 UTC
From: R&D Smith <rdsmith@recorder.ca>
Message-ID: <xbWM7.2$4j2.759842@localhost.localdomain>
Source record: 153910

I am monitoring the OPP (Ontario Provincial Police) They have 9 different towers with an abc in each division so itd would go 1a 1b 1c, 2a 2b 2c and so on and every tower has a mobile and a base frequency or a frequency and a mobile where the frequency being the tower. ex. 1a mobile 139.470 1a base 141.390 1b 139.185 1b base 141.195 and so on.... and it says that all opp frequencies use CTCSS PL-TONE 107.2 Hz. Set your CTCSS tone to this to get rid of the computer generated squawking.... but its seems to be not working , i have a BC 245 xlt radio and i can pick up there mobile repeaters but i have a hard time getting rid of the squawking.. so could a OPP fellow monitor or someone who knows what im talking about please help me.... I have the winscan software and its has a spot where i can set the pl tone to anything i want os this apply to my scanner,, i am assuming so... so please help

Cecil,
I wouldn't dream of discouraging anyone from
building their own equipment. I ~do~ believe you
should explain that some parts are harder to come
by than others, high voltage capacitors being one
of them. You may be correct about 'Fair Radio',
and then again you may not. I've seen times when
they did not have the parts needed to build a tuner.
So, what I said about being a 'scrounger', and the
availability of parts in some places is still very
true. Personally, I would rather know that 'going
into' a project than finding out half way through.
If you stop and think about it, there are very
few high voltage 'anythings' being sold any more,
as there was 10 - 15 years ago. With the advent
of solid state, high voltage 'doodads' just aren't
as prevalent, which is normal. So I think my post
was pretty good advice, I'm sorry if you don't.

I will be putting up my antennas soon and need mast recommendations. Don't know if I need chromally or not. I plan to put up a TH-11(12.5 sq ft windload) and a linear-loaded 40m, 3 ele yagi (9.8 sq ft windload). They will have about 12' separation. Can I get by with galvanized mast, with .25 wall thickness??? Thanks for your anticipated reply.

I've missed some contrubutions to this thread. My service provider is not the most reliable. He probably gets his formulae from 1930's editions of Practical Wireless.

But let us all face up to the fact, unless one is designing inductance standards which already exist anyway, plus or minus 7 percent accuracy in calculating inductance is good enough for most engineering purposes and more than good enough for amateur purposes.

Radio is by far the most inexact of all the sciences !

>Any and all help will be greatly appreciated.

At the risk of getting flamed I must ask, are you sure you need a
tuner?

What is the particular application that requires the tuner and is
there an alternative that makes one unnecessary.

The most efficient "tuner" is a matched antenna. The operational
convenience of no tuner is---well---convenient.

For instance, I flitted around 80, 40 and 20 meters during CQWW this
past weekend looking for band-countries. I have a Yagi on 20 and a
parallel-wire dipole for 40 and 80. My "tuner" is the pi-net in the
Drake L-4B.

So to change bands, I had to fiddle with "only" three knobs. Imagine
using a tuner too and having six adjustments to make for each band
change. Bah.

Tunerless in Tucson,

Wes N7WS

FAA issues aside, go to your town hall and talk to the building inspector and zoning officer. I just obtained a building permit last spring for a 60 foot foldover, and I live in a AAA zoned residential neighborhood. Having two acres of land helps, however...

Paid the fee, no hassle, no problem, and passed all inspections without incident. The only thing they were concerned about was cell phone towers coming into town.

You could always go with a 2m to 6m transverter.. they run pretty cheap, but
if you are like most hams, you only have a 2m FM rig, so you'd be restricted to
6m FM... the MFJ-9406 is a nice little 6m SSB radio and you can usually find
them used fairly reasonable.

Tom Bruhns wrote;
"I`m not sure why your value is coming out so high ... but suspect it`s because the coupling between the two halves of the thing you calculated isn`t anything like unity."

That sounds reasonable to me. I suspect that`s why Terman and ARRL quit calibration where they did. When coils get long and skinny, coupling between ends of the coil must suffer.

Terman`s F chart is for length to diameter ratios between 0.3 and 3.0.

I took the coil as being 20 inches long and having a diameter of 5.25 inches. That gives an L/D ratio of 3.8 which is off scale. I chose to do half the coil and multiply by 4. L/D is then 10/5.25 = 1.9
For this ratio, F = 0.011

I expected crude results, but expected to come closer than I did. I underestimated the decoupling that so much axial space provides. If only I had thought back to my experience with coupling loops, but I didn`t.

Sometimes I just look for the meatgrinder to shove in the meat and come out with the sausage.

Best regards, Richard Harrison, KB5WZI

Fortunately the city I built in does not require any special
conditions for a ham tower. Nor does the subdivision have any
restrictions on towers. I had the base poured with the driveway as
part of the house building permit, and the building inspector signed
off on it.

Ed,
I think I'd start looking at towers. You might find
a 'mast' that would hold your antennas, but I really
doubt it. It isn't the weight, but the 'twisting' forces
on the mast that would be a problem. By the time you
find/pay for a mast strong enough, you might as well have
bought a tower...

The answer to the question is: not well. The feedpoint impedance will only be low where the wire goes through odd quarter wave resonance. Everywhere else, it will be high and usually reactive. That is an excellent location for a remote tuner, otherwise it is a crapshoot, not favorable to you. The other alternative is to feed it with open wire parallel line, as discussed on here a few days ago, and put the tuner in the shack.

2871. Hamstick Antennas on 75M and 160M

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-28 02:39:38 UTC
From: Tony Bogusz <tony_b@ameritech.net>
Message-ID: <K7YM7.4817$Rw2.3392530@newssrv26.news.prodigy.com>
Source record: 153822

2 Hamstick topics for the group:

1. Where's the best frequency range to use my 75M Hamstick's 25KHz of available bandwidth for an occasional QSO on my hour long commute home from work in the evenings (North Suburbs of Chicago)??? I hear a lot of the same groups nightly using the 3875 to 3905 range , but few breakers, random QSO's or CQ's.

2. Does anyone have any experience using the PHF160 Hamstick? Also, has anyone out there tried 160M mobiling at all?

The PHF160 seems expensive @ about $100, but Christmas is coming......I'm just concerned that the thing might be no better than a 100W lightbulb for radiation efficiency. Will I be able to work the stronger stuff I can hear?

I've been very pleased with my other Hamsticks for 40 thru 6 meters. (Good performance . Low price per band too.) My thanks to the group and Happy (upcoming) Holidays!

Tony, W9MT

The question would be more likely to get an answer at one of the scanner NGs. Antenna design isn't going to sort that mess out.

>Does anyone have an online source for where I could find the schematics
>and parts to build an antenna tuner?

Here is what I did. Used a "T" type configuration. Got the capacitors from Ten-Tec, kit form, part #1207 @$39.00 each. Wide spacing, ~50-500pf. takes about an hour each to assemble. Got 22uh roller inductor from Radioshack.com (MFJ unit $69.00). May need to get knobs and coax jacks at RS also. Mount all this on a piece of 1/4" plexiglass and away you go. Ran about 500 watts thru mine so far, but feel it would handle more depending on what you are trying to match.
An enclosure would be nice, but will add the $$ to the final tab. You certainly don't want it where someone could touch exposed parts while transmitting. Enclosure helps with rf containment also.
I think you would spend >$300 on a similar commercial unit. A tuner is one thing an average ham can find the parts, build it, and have something that is really useful. I use mine to match an attic dipole fed with 450 ladder line on 160-10m.

I ran into a weird ruling once in a city in NC. If I recall the story correctly, the tower must be located 1/3 of its height away from the property line. I forget if that is a generic setback code. But they considered the GUY WIRES as part of the tower!!! requiring the same setback for the anchor points.
Stupid me for asking...I went ahead and did it anyway with no repercussions.

>
>What is the particular application that requires the tuner and is
>there an alternative that makes one unnecessary.

Gosh Wes, you do need that tuner in the L4-B. As you know there are countless applications where an external tuner is the only way to go. Solid state-broadband rig that must see 50 ohms resistive or they fold back power is one, the same thing, but with an auto-tuner that can only match 3:1 type mismatches.
All of my operation is thru an external tuner because all I can erect is an attic dipole-feed it with 450 ladder. I adjust the tuner with a 259b, and work 160-10m. Only fiddle with 3 knobs on the tuner this way, almost like you.
Man, I long for the old days!

Hi Dale,

I once used a 5BTV roof mounted when I was living in SC. I put up some radials strung out over the roof and it helped (almost none of which were in a straight line). And I can appreciate what your position may be, having been an apartment dweller for the last, oh, maybe 20+ years.

Anyway, I want to ask if maybe there is a way for you to lay the radials out such that they didn't have to extend onto your deck? Plus I once read an item that talked about using a metal screen mesh material under the antenna as the 'radials'. Seems it said that the need for a quarter wave 'length' in any one direction was eliminated if you could get several feet of this stuff radiating from around your antenna base.

Just an idea.... best of luck!

Well, the local code didn't specify 'falling anchors' but that was the interpretation of the department personnel. I just assumed that they were in the 'setback distance mentality mode' for any type of construction.

Tony,
I'm afraid that a 'Hamstick' isn't your 'best'
choice of mobile antenna fo 80 or 160 meters. They
do fine on the higher bands, but as the frequency
goes lower, so does the 'Hamstick's efficiency. I'd
say that on 80 meters it would be marginal, and on
160 meters, just forget it (sorry 'bout that).
As to what part of the 80 meter band to tune the
antenna, the best advice is to listen, decide which
'group' you think you would enjoy joining, and then
do so. Not much help, but you know your preferences
much better than 'we' do.

Pete,
I have to agree with 'Crazy George', using a balun
on a longwire just isn't worth the trouble. Much simpler
to just continue the wire into the shack to a tuner. In
either case your going to need a very good ground system.
Good luck with it...

Source record: 153840

First off, Thanks to all for all the replies.

Wes: I need to tune a G5RV for most/all HF bands. I need to be able to do this so I don't blow my IC-706MkIIG up while trying to transmit and do the things HAMs do. I need to use the G5RV because the landlord is somewhat picky about having wires running all over the apartment complex. (It was hard enough to convince him that the G5RV would be an improvement over the 20 and 40 meter inverted V's I had up!) I won't be running over 100 watts.

If I had the real estate, and if I didn't have a landlord, I would agree.. multiple antennae tuned for the specific bands in need would be the best solution. However, for this apartment dweller (and a basement apartment at that), a G5RV and a tuner are all I have.

What prompted this question in the first place is that the (borrowed) tuner that I've been using needs to go back to its owner, and I need to find an inexpensive solution (money's been tight) to this little problem.

Hope this clears things up...

Hi OM,

Wes, I think, was writing to the larger audience.

Asking for A schematic for a tuner runs the same risk as asking for a
recommendation for an antenna. That is, many answers that leave you
with more choices, not less.

There are a world of designs for what is otherwise the ubiquitous
"tuner." One of them, a link design, is often attended with a hushed
reverence. The more common units are reviled for not adequately
covering 160M; and so on down the line. There is the debate over Pi
filters vs. T filters - the arguments are often less than compelling.

Then I've noted the "debate" over the merits of roll-your-own over
off-the-shelf. The oddest argument I've seen is you can't afford the
parts but you can afford the unit (one wonders how anyone can make a

profit building them in the first place!). We all discount our time (thus the amateur status) so the economics of it demand roll-your-own unless there is some outright bargain begging to be bought.

Get yourself a project box for a chassis (an 8" square cake or meatloaf pan is traditional); two connectors (gozinta and comesouta), an air variable cap with at least 30 plates; wind your own coil with about 30 turns (2 or 3 inches across 4 to 6 inches long) with taps every 3 turns going to a 10 position switch. Connect the two components between the two connectors.

If you can find something cheaper than the cost of these individual items, slip your mind into neutral and buy it.

Of course time and DX waits for no man, and the off-the-shelf solution does provide an answer now when the conditions call. I have only hinted at a design. The next iteration would be to add a switch that re-arranges the relation of the components into all combinations of series, parallel, and single selections between the two connectors. I would add that this new switch will be almost necessary to attempt to accommodate any wide variety of SWR conditions.

Or you could ask your buddy for the schematic to his tuner. If he doesn't have one, pop that sucker open and draw your own! Skip all the parts that are meter related and you should find it fairly simple. Shouldn't take more than an hour.

>
> Paul (Kl7JG)

There is one in the eznec antenna modeling program as far as
dimensions. It's the NBS yagi that is in the demo. It's already set
for 6m,"50.1 mhz" and you could fine tune it to any frequency. I built
one from 1/2 inch copper tubing that I brazed together as a one piece
yagi. The boom is also 1 inch copper. I made the gamma match from 3/8
copper tubing naturally...:/ It works fine, and tuned up under 2:1 swr
the first time I tried it up. Whatever plans you use, use the exact
dimensions called for with the tubing etc, unless you recalculate. I
think it cost me about 21 $ for the hard drawn copper at home depot.
You could use other types of tubing. I would prefer aluminum actually,
but I didn't have any and the home depot is around the corner. I've
got an oxi-acetylene torch so I just welded the whole thing together
one piece. It's good for about 9.5 dbi gain and a f/b of about 10 db
with the NBS spacing. It's set up for max gain. I think eznec should
be at eznec.com I think. MK

TexasTower In my humble opinion is a GREAT place. I've bought several towers from them over the past 9 years, and loads of antennas, and radios. I've also bought from HRO, and AES, and the HamStation. I've NEVER had ANY problems with Texas Towers of any kind. Everything I've ever ordered from them was via the web, or had to be shipped...as I have lived in New England most of this time.

I just wanted to put my two cents worth in about Texas Towers IMHO that are a GREAT ham resource. As are HRO, AES, and others.

I've always had an excellent experience buying from TT.

Use the one specified in the National Electrical Code! This will depend
on your voltage and the current you expect to use. It probably will look
like the one on your electric dryer. Make certain that it does not look
like the standard 110V socket!

Thanks Rich... These "hints" have got me to thinking a little...

There's no real rush to this. I want to build one so I can say I did. I was able to borrow another tuner for the time being (same model, MFJ 941D) and all the tuning points changed. All of them. Of course, now I'm able to tune 160 and 15 and 6 just fine, whereas with the old one I was unable to reliably tune 15 and 6.

At any rate, I'll be thinking about my "design"... maybe inside of an old coffee can.. and I'll let you know what I come up with.

Thanks again for the input.

2902. Apartment antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-28 15:53:35 UTC
From: Richard Malone <malone1956@home.net>
Message-ID: <3M7N7.63349$Ze5.34480351@news1.rdc1.md.home.com>
Source record: 153854

I'm getting back into HF after many years of inactivity. (Lost the radio room to nursery) I have just purchased a Kenwood 520 and live in a 3rd floor apartment. I have no access to any roof or attic, however I have a balcony (5' x 13') with a aluminum railing. I have read about the Cliff Hanger (Slinky Antenna) and a little about the DK3 Screwdriver. Does anyone here have experience with these antennas, or can someone offer another solution.

Thanks!
Richard, n3fif

2903. Program DIPOLE2

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-28 15:57:08 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <9u43nrdvo1@neptunium.btinternet.com>
Source record: 153786

NOW AVAILABLE ** Program "DIPOLE2.exe

An update of programs Dipole1 and Varney.

DIPOLE2 analyses the performance of any HF dipole of any height and length, at any frequency, plus a balanced feedline of any impedance, length and attenuation, plus a balun of any impedance ratio, plus a coaxial line of any impedance, length and attenuation, plus a "tuner" with an L-matching network. (An L-match always has a lower loss than a T or Pi).

Computed results include R+jX input impedances of antenna, of balanced and of coaxial line. Antenna radiating efficiency. SWR and loss in balanced line, coax and tuner. Tuner L and C values to match system to 50 ohms are computed. And, of course, overall radiating efficiency.

If either coaxial or balanced line is not needed set the unwanted line length to zero. (Use a long length of coaxial line with multi-band dipoles only if it is an absolute necessity).

This program tells the user immediately the consequences of changing something at one point in the system which affects something somewhere else. For example, if it is asked should a 450-ohm transmission line be increased or decreased in length to provide a more accurate 50-ohm transmitter load impedance, the program will tell you not only which way to go but the actual change in length which should be made. See Cecil's W6RC website for practical implementation. It will also advise whether a change in feedline impedance might be a better option.

Facilities are provided to search for resonant frequencies of an antenna plus feedline. It will be noticed they are not harmonically related. The effects on resonant frequencies of varying in small increments the lengths of dipole and feedlines can be investigated.

DIPOLE2 is about 70 kilobtyes. One file only. Download from website below in a few seconds. Not zipped up. Run immediately.

|Wes, I think, was writing to the larger audience.

Thank you Richard. That indeed was the case.

My intent was to get the questioner to---using the buzz phrase du jour---"think outside the box." (No pun intended)

It seems to have become the norm to solve a lot of antenna problems with a "G5RV and tuner combo". I expect to see Radio Shack follow McDonalds and offer a Number 1 G5RV combo that can be super-sized to handle 1KW for just $139.95.

Seriously, the solution might be a random length wire and a tuner but then again with a bit of thought the answer might be something else a lot less complicated, lossy and costly.

You can purchase a 17' X 0.25" wall galvanized steel mast from Texas Towers.
See URL:
http://www.texastowers.com/steelmas.htm
Since the mast is heavy and 17' long it will be a significant cost to ship.
However, for your requirements, I would go for it.

A J-Pole and an End-Fed Zepp are essentially the same
antenna - 1/2WL vertical section plus 1/4WL parallel
matching section. For 11m, that would be approximately
17.3ft of antenna fed with approximately 8.2ft of
450 ohm ladder-line.

> Sometimes I just look for the meatgrinder to shove in the meat and come
> out with the sausage.

;-) Well, I commonly do that too, but occasionally I'll check the grinder against some standard...

Here's a little mental 'speriment for you. I'll do it with the good old n^2*r^2/(9*r+10*l) formula, but invite you to try it with Reg's coil program, or coil.exe from saratogasoftware.com, or the F*n^2*d formula, or some other...even measuring them??!!

Imagine a coil where d=l...let's say 16 turns, 1" long and 1" diameter (0.5" radius). Then the net inductance from the formula is 4.4uH, but the inductance of half of that coil is 1.68uH, and 4 times that is 6.7uH, or over +50% error. And that's for a coil that's NOT very long compared with the radius. The coupling in a solenoid coil really isn't all that high, unless you put in a high permeability core. Actually, I just did this in Excel and let it do a range of lengths; the error ranges from +22% at d/l=4 (pretty short coil!) to 52% at d/l=1 to 69% at d/l=0.5 to 85% at d/l=0.2

I certainly don't mean to belittle you in bringing this up...in fact, I thank you for it, cuz it gave me cause to "check the meatgrinder" in a way I hadn't before, and point out to the group that the coupling in a solenoid really isn't all that strong. Actually, if I'm not mistaken, one of Reg's most recent programs addresses just this sort of thing in the context of coupled resonators. Note that for high Q resonators, it doesn't take a very high coupling coefficient to get critical coupling ("flat-topped response").

Cheers,
Tom

hey richard
what i would do is check out hamstic they sell a mount just what you need you take 2 hamsticks for one band and screw them into this mount and it turns them into a dipole of sorts for that band then what i would do is get a weighted microphone stand and attach that mount to the mic stand so you can place the thing out on the balcony
good luck

Yes, you should be fine just linearly scaling the lengths and spacings
by the frequency ratio. If you push it very far, you should also
scale all the wire (element) diameters, but I doubt that will be an
issue here.

I could only guess at bandwidth; different designs are different.
It's unlikely you'd notice any big changes at +/-1% from the optimum,
but some designs are much broader band than that. You might query the
folk associated with that site. I didn't look closely enough to see
if they had any bandwidth stuff mentioned there.

For modelling, you probably will find that the driven element length
is relatively unimportant to the gain (and pattern). If you want to
model it for gain, just use a center-driven dipole as the driven
element. For matching to the driven element, if you start with the
know design and allow for some adjustment, you'll probably be fine.
As has been pointed out here many times before, it's almost never
worth getting too hung up about SWR, if you can get it down below
1.5:1 or so.

Cheers,
Tom

Towers should not fall. That may have been a code written to
protect aesthetic property values. Just like setback regulations for
buildings, etc.

Well, maybe to be in line with drakes likely instructions to try to keep the match under 2:1 swr. But really, as long as the amp will tune the load, and the loading control is still within the loading range without being all the way one way or another, he's really ok. I've done the same thing at lower powers using my henry. Same thing for my tube final TS-830. If it loads up, and is within loading range, that as good as you really need to be. The tuning circuit is acting as a tuner to match the output to the load. Adding another tuner to get it even better won't help a bit as far as the output. It only makes you feel better about the mismatch the finals are dealing with. I'm kind of the same way, I don't use a tuner unless I really have to. And I don't waste money on internal radio tuners either. If you are going to use a tuner at all, a real outboard tuner is much better. MK

Use the style that is found on most home 220-volt airconditioners.
These look like a regular 110 volt outlet except the openings are
inline instead of parallel to each other. They are rated for 20 amps,
which should handle any legal ham amp.

Your local hardware store should have them.

Peter

I beg to differ with you, I have tried using a longwire and just run into the shack with a plain wire, and with co ax with the shield grounded and also tried hooking the long wire to a magnetic longwire balun and running co ax from the balun to the radio. By far using the MLB comes out on top for best signal. Often by as much as 2-3 s units.

2922. Questionable Metz Mobile Ant?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-28 22:41:16 UTC
From: lbrty4us@aol.com
Message-ID: <20011128174116.13655.00003351@mb-dh.aol.com>
Source record: 153773

Was checking a used Metz mobile ant for resonance, with odd results. Metz was a respected maker (now an SK hear), and this thing looks like a 20M base-loaded thing. But it resonates (and also really puts out the RF from a sig gen) at about 15.8mhz, & seems fairly dead on any of the ham bands as a radiator. WTF do I have?? Has a serial number but no model number.

2923. Re: What kind of 240 plug on linears?

Here's a generally useful site that links to lots of mains-related
answers: http://www.epanorama.net/wire_mains.html

In particular, you can find the standard NEMA socket configurations
at:

http://www.leviton.com/sections/techsupp/nema.htm
and
http://www.quail.com/locator/nema.htm
(and probably some others!)

Personally, I'd go with the 250V 20A grounding one, NEMA 6-20R. Note
that it will accomodate either a 20A or a 15A plug. 20A@240V =
4800VA, and that seems like it should give enough margin for most
amplifiers. (But good practice is to plan for ~20% more capacity
than the maximum expected load.) You could go for a feed that could
accomodate higher current in the future if you end up needing it, and
then only have to change the socket and breaker. 10 gauge wire would
normally get you to 30A, unless there are extenuating circumstances,
and gives you lower drop under load for your 20A service than the
default 12ga would. Of course, if you know the amplifier of your
dreams will take 4500VA, you should probably go ahead with the 30A
service to start with. FWIW, I'd also put in at least one dedicated
20A 120V circuit to the hamshack, and plenty of outlets.

Cheers,
Tom

It appears to me that the same problems & issues and methods are being faced and/or employed as we were looking at in 1956(?). And likewise, everyone is adept at saying what *doesn't* work well (and little of that has changed as well). What really is the best, or state-of-the-art today for mobile 75? All the new stuff I see looks like re-creations of the same old ideas, many of which weren't ever so hot on the air (but at least they were cheaper, or individualitistically charming then if homemade). I see no point in automating the tuning a 50-year-old somewhat inefficient antenna, for example, like an old whore with new clothes on. Has anything new been done in 45 years, that really radiates much better? If not, what is the consensus of "best" out in the real world (and not in the software or underwear)?

Antennas are one thing that hasn't yielded to miniaturization and those
rules of physics haven't changed in over 100 years. The 75m mobile antenna
shootouts I've attended all indicate that a hi-Q bugcatcher with a large
top hat and no jumpers on the coil or a well-designed hi-Q screwdriver with
a large top hat are top dogs on 75m mobile. I personally use the HS-1600,
a higher-Q version of the HS-1500, with a six foot diameter top hat.

I have not used one, but since it started life as a CB transceiver, it probably does not have the specs of a rig that was designed for amateur service, to begin with.

QST reviewed it, and said its performance is sorta middlin'. But for 6 meters, that's fine when the band is open.

A used rig for 6 meters made by Yae**-Ico*-Ken*** might be a better way to go.

Jeff,
Just exactly what is a 'magnetic-longwire-balun'? A long wire isn't 'balanced' to start with, neither is a coaxial feedline, or a 'single' wire feedline. So, magnetically or not, what are you 'balancing'? Or is a 'magnetic-longwire-balun' an impedance matching device? If so, how does it know what impedance to match to what, how do you adjust it? And if it is an impedance matchin device, isn't that the same thing as a tuner?
The 'magnetic-longwire-balun' began being advertise a couple of years ago. I asked the manufacturor to explain how it worked then, and never got an answer. I'm still waiting for an explaination of how any 'balun' works with a longwire antenna...

LBRTY4US,
If it works well, I, personally don't care if it's
a 'new' idea or an old one. As far as that goes, your
views hold true for automobiles, too. Aside from a few
new construction material, what has improved in the
'car' market? Same basic design as in 1920, aren't they?
If you will come up with a 'new' super-duper mobile
antenna, I'll sure give it a try... but I'm not throwing
away my 'bugcatcher'.
'Doc

Here's a link to my website with info on my 5 band Hexbeam installation.
http://home.sprintmail.com/~sentek/hexpage1.htm

If you have any questions after viewing that info, feel free to contact me via email. My antenna has been in the air for over 18 months with no problems. In my particular situation, it was the best solution available for complete top to bottom coverage of the 5 bands. If you don't operate CW and have no restrictions on the size and height of the installation, then you may find one of the log/yagi arrays more attractive. I also like the quad antennas, but find them to be rather high maintenance if you live in a windy area.

>Ed NI6S

Hi Ed,

The answer is an unqualified NO.

Your TH-11 itself demands a yield strength of 119,000 PSI at 10 feet
separation. Your best bet for that antenna alone is 4130 CDS Chrome
Moly (0.375 inch wall, by the way) which is rated between 110 and 120
KPSI (and at notably lower than 12 feet).

Two beams is just asking for trouble, and hell to untangle from up on
high when the wind whips your two beams into pretzels aloft.

> sweat it.
>
At times I've used several 300 foot runs of the 3/4 inch stuff and it worked
very well. Connectors are relatively easy to make, but a lathe simplifies
things greatly.

I use a 3/4 inch brass coupling cut in two. I bore out the small inner
diameter of the coupling to fit the outside barrell of a PL-259 and solder
in a brass PL-259. Use a tubing cutter to remove the outer jacket and the
inner conector will just fit into the pin of the PL-259. It solders easily
as the center conductor is copper plated. I do use a bit of pentrox in the
compression ferrule.

For the 1/2 inch stuff just use a 1/2 inch to 1/2 inch compression
coupleing. The coax goes into the one end and the back end of the PL259
goes into the other. Tighten and you are in business.

What you are hearing is what the OPP put on there to stop you from
listening. I am not too familiar with that scanner but it must have a CTCSS
decoder to get rid of the annoying squawking. Set it for 107.2 Hz and make
sure the tone squelch is on. You shouldn't hear a peep until the base
transmits. I'm in Kingston and have no problem monitoring them on my
HTX242.

Good luck

Well... there are many things that can happen to a radio between the factory and the customer.
I think you will find that whether Texas Towers, or AES they will have the same shipping and return policy on most rigs.
They're re both good outfits to deal with and both have the customer pay the shipping back to them. There may be some exceptions, but in general that is the way it works.
I purchased almost all of the tower accessories from Texas Towers as they had them in stock. I purchased a bunch of antenna accessories from AES as they had them in stock. I purchased the 756 Pro from ComDac as they had one at a swap for a good price.

I asked for solder type N connectors, but we had a bit of miscommunication and I ended up with the compression type. They (AES) shipped out the proper ones right away, but I had to pay for them. I get the money back from the first ones when they receive them back I also have to pay the shipping back.

I have no problem with that.

Both companies are open about their shipping and return policies. I have purchased quite a bit of *stuff* from both companies over the years. ComDac in Michigan is another good company to deal with. Not as large as Texas Towers which is not as large as AES, but a nice family operation with which to deal.

BTW, I have no connection to, or interest in the operation of any of these companies. They are just companies from which I have purchased ham gear and accessories and have had no complaint about their practices.

Source record: 153797

Unless you plan on something on the order of an old broadcast transmitter, you want a 20 amp/ 220 volt outlet with a 20 amp breaker feeding it through 10 Ga. wire. 12 Ga. will pass code, but 10 will provide a tiny bit less drop for those picky amplifiers. This outlet will be similar to the U-ground 110 outlet, except one slot will be rotated 90 degrees, and the other will be T shaped, as it will also receive a 15 A plug, or the 20 A plug, so you are covered. The NEMA reference number for the socket is 6-20R.

Every feed line into the shack here has a 6 foot jumper to the rigs from the
"bulkhead" containing the lightening protection. I use LMR 400 from the
shack all the way to the antennas (bout 228 foot runs) Closer to 300 feet
for the wire antennas.

I took out all the 9913 (about 600 feet) when I put up the new tower.
Actually I started replacing it when the old tower took a direct hit which
blew the coax seal and liquid tape right off the connectors. It even took
the silver plating off them. About two hours later I had water running out
of the bottom on my 2-meter rig (It was a one piece run from antenna to
rig). Other than kinking a couple of pieces, that was the first problem I
ever had with 9913 and I'd been using the stuff since a bit after it came
out.

> into the feedline that may be a problem. Is it so much further to the
> shack from the entry point that you wouldn't want to use RG-8X straight
> thru?

There was no mention of frequency or power levels. For low power...on the
order of a coupleof hundred watts, I'd use "good" RG8-X all the way to the
rig to the outside connection. IF OTOH the station is going to be running a

KW then I'd find a big drill bit and run the larger cable all the way to the rig. A KW into RG8-X would be pushing your luck a bit...Although it'd might work for HF if the SWR is very low.

Ed:
It will depend on the alloy, as you suspect. That load is way beyond galvanized water pipe, so the galvanized comment is a red herring. High alloy (my steel reference books are elsewhere, so I can't specify a specific alloy number) will be required, and galvanizing against rust failure is always desirable. Somewhere there are equations which will allow you to calculate the bending moment at the top support at whatever wind speed you wish to survive, and given the size of the mast, then you can calculate the yield strength required. Any good mechanical engineering handbook will walk you through the process.

> however...
>
> Paid the fee, no hassle, no problem, and passed all inspections
> without incident. The only thing they were concerned about was
> cell phone towers coming into town.

I had pretty much the same experience.
The only difference is that it's only the supporting tower height that pertains to the setback rules. I was told not to worry about the mast and antennas.

Here the only two things to worry about are setback (which is legal) and towers over 80 feet need to conform to the proper engineering to withstand the tower loading for both wind and weight. A safety issue.
BTW, the construction cost goes up exponentially from about 60 feet if it conforms to good engineering practice.

I walked into the office, told them what I wanted to do, showed the inspector the Rohn catelog with the engineering figures , paid the fee and walked out with the permit.

I asked the two adjoining neighbors if they minded the tower and both said no.
The cable company had to sign a contract that they would fix any interferrence problems and not blame amateurs for any interferrence to get into the townsship.

I have had a T2FD antenna by B&W. It is a folded, broadband dipole. It literally stinks at 80 and 160 meters. It's probably useable on 40 and higher freqs. It will provide a decent load for the transmitter, but efficiency is very, very poor. Jim W7LS

I've got two of 'em.

One at the house about 30' up, other is 'trans-mobile' with a RS tripod
in the truck. Both driven by TM-V7As.

Love 'em.

Arrows are the only commercialy produced ham antennas I've played with
that'll not only survive a Wyoming winter, but several of them. Many
severals of them.

Performance? Well, performs like a J-pole - on both bands.

Nothing bad I can say about 'em.

Richard,

Try this website. Harry is a great fellow with all sorts of good ideas. He has dozens of homebrew projects up for view, including three antennas suited to just your QTH. He lives in an apartment with a balcony like you describe, and claims acceptably good results using a couple of homebrewed verticals mounted on the balcony railing. Good luck!

Source record: 153807

There is another basic aspect of antennas Location! Location! Location! Just like real estate where an antenna is located is as important as to what kind it is. Do you have any hills in the way? VHF signals go around hills a lot easier than UHF does.

so to determine whether it is a UHF/VHF antenna look at the front of the antenna (the end with the shortest elements) and see if they are about 6-9 inches long.

In terms of the type of coax you have, there are many varieties of RG 59 and depending on the age, it will have a large range of losses. So it is better to just replace it with RG6.

I have made a proposal of a new newsgroup alt.tv.hdtv.antennas to help out those people who are having trouble with there new HDTV sets and getting local reception. It has been suggested that people look at this newsgroup for advice. while there are many experts here on antennas, I think it would tend to confuse non hams all of the other types of antennas that are being talked about here.
I would like the regulars input on this subject.
Also if you would please respond in alt.config.

if you already have a TV antenna on the roof, I would just split it off
and run another cable to the back of the computer.

No, but you could figure it out by measuring the length of the driven element. It should be half of the wave length. So measure it, convert it to meters, double it, then divide 300 by the length and that should give you the frequency in MHz.

what do you mean by not working very well? It could be the radio, it could also be the whole concept of CB to start with. In the city the bands are full of noise and this causes the range to be even shorter.

I have downloaded several modeling programs including Antenna Solver and MM Antenna Analyzer, and dipole 1. Dipole1 is the most helpful in the what if catagory.

Are there tutorials for the beginner to help me get through X1, Y1, Z1,X2,Y2,Z2, etc? The help on these aren t too helpful. All I know is how to cut a dipole to 1/2 using 492Xvel/f Mhz and the very basics of feedpoint impedance.

After looking at these programs, they make the smith chart look simple.

Do you know how to graph? +X can be east, -X can be west, +Y can be north,
-Y can be south, and +Z can be up. A wire from X1,Y1,Z1 to X2,Y2,Z2 is
simply a straight wire run between those two 3-D points. A 75m east/west
dipole at 40ft would be -65,0,40 to 65,0,40 OR 0,0,40 to 130,0,40. A north/
south dipole would be 0,130,40.

Ditto to the opinions expressed by others in this thread. The only thing different, really, is the
"Screwdriver" antennas which allows one to have a resonant antenna without getting out of the
car on all bands. For the most efficient, I would have to weigh in on the side of the Bugcatcher
for single-frequency work. THAT hasn't changed at all; Hi Q center-loaded coil using, either
the longest feasible whip or the cap. hat. In my own experiments, I have found that there is a
limit on how large a Bugcatcher one can truly use. I have seen those "monster" 6 inch coils/hat
combo, and, for the life of me, I can't see how they use them. When the Q of a mobile coil gets
just SO hi, its sensitivity to the surroundings goes thru the roof such that when you resonate it in one
spot, it goes out of tune when you move the vehicle! What that means is, when you are tooling along the highway, the coil's surroundings change so much, that the thing is out of "tune" much of
the time leaving the op dead in the water--or losing that rare DX station he wanted to work. That
tells me (and I am certain some will disagree with me) that 3-4" dia is about the max I want to go
with a coil. Enter the screwdrivers. Many of them are efficient enough to be affected by surroundings as well, but the great thing is, if you notice your antenna, or signal output, seems to be
substandard, you can adjust the thing while underway. It usually takes only a jog or two on the control switch. So, there hasn't really been anything new under the sun in antennas except the screwdrivers provide a flexibility not previously available

I installed a well thought out dipole for 40 and 20 mtrs. I also installed
a random length (100 plus feet) end fed that rubs 3 trees. It's hooked
to a choke balun with ground and 50 ft of coax into a tuner with good
station ground.

Guess which antenna I have the most fun with.

The two work equally fine on 40 and 20 mtrs but the end fed will work
80 through 10 mtrs at 1:1 with help from the tuner of course.

An old timer told me to read all I wanted to about antennas but when it
comes down to it, it's whatever works for me. I guess I'm just lucky.

If the receiver has a low input impedance and the AVERAGE impedance vs frequency looking into the random wire is 600 ohms, then a step down transformer, on the AVERAGE, taking one band with another, will be beneficial - whether there is any coax used or not. The presence of coax doesn't have much to do with the question. Coax merely shifts the receiver input to another location.

A balun is not necessary. An auto-transformer is OK for aproximate matching of long-wire antennas to receivers.

But since the benefit to the user of a better impedance match is only an increase in average received signal strength (a minority of signals will actually be weaker) and at LF to HF it is signal-to-noise ratio which matters, the balun manufacturer benefits most.

On the other hand, with a low impedance receiver, if the antenna is just a short whip a step down auto-transformer (NOT necessarily a balun) on a small ferrite ring might be beneficial at all frequencies where the antenna length is less than, say, 1/20th of a wavelength. The danger here is that signal levels may fall lower than internal receiver noise.

Jerry,
I've used both the 'standard' size and the 6"
coil on the bugcatcher. I haven't noticed any
difference in performance between the two. (Also
use a 'cap-hat'.) Of course the 'tap' positions
change, but I would expect that. Now, if I can just
find a 'ball' mount that lasts for longer than 6
months I'll be doing okay...

Brent,

Sorry to hear the first radio was faulty, but your complaint should be
with the manufacturer whose quality control was poor. Why should Texas
Towers incur additional cost for someone elses mistake?

As for my experience with Texas Towers' customer service, they have always
been very helpful. They recently agreed to take shipment of a ton of
aluminum our contest club ordered from a distributor until and store it
until we were able to pick it up. They were not involved in the purchase
and received nothing for their help but our appreciation.

Hope you have better luck next time.

Ed,

You need to find out the minimum wind speed for your county. You can check the Champion Radio web site for this information (www.championradio.com). Once you know the wind speed the mast should handle, the mast properties (diameter, wall thickness, yield strength, etc.) can be determined. Champion radio sells software that will calculate mast and rotator requirements for about $10.

I would suggest going to www.contesting.com and doing a list search from the TowerTalk list archives. There is a wealth of information there.

Rick,
You have to understand that this particular part
of the country is at least 20 years behind the times.
If it's new, or even fairly recent, you won't find it
here. You have to either go somewhere else to find it
or order by mail.
The second thing you have to understand is that
I'm 'cheap', a 'tight-wad', 'conservative'(?), a typical
ham. I mean, there ought to be ~some~ way of 'fixing'
it, right??
And lastly(?), I'm too lazy to do it till I get
'P.O.'ed, then I'll fix it. (Besides, it gives me
something to complain about!)
Actually, I'm looking for a 'slab' of some kind of
good insulation material to make a 'base' for the ball-
mount. Haven't decided what would be 'best' yet, and
at the monent, there's no real hurry.(see excuse#3)
And, considering that this is more than you ever
wanted to know about all this, I'll quit...

For most of the work I do, it is indeed fine to know the initial inductance of a coil, as installed, to within a few percent, and just plan to make adjustments. On the other hand, I'd really like to have ways to calculate the inductance of the coil itself which have a little better accuracy than I normally expect as a result of mechanical errors when I make the coil. For example, I can easily measure the diameter of the former on which I wind a coil, to about .04mm (.001 inches). I can measure the length of the coil to a little closer than a millimeter just by eye against a scale, or quite a bit more accurately if needed. So for a 25mm diameter coil about 25mm long, I could incur errors because of coil size only in the 2% region. Since I do quite a bit of work with coils around that size, then, I'd like formulas for inductance that don't degrade the accuracy to which I know the inductance by more than a percent or so. If I have an 8% error budget, I don't want to use up 7/8 of it because my basic formula is in error by 7%...there are too many other things that will eat into the budget.

There are additional variables, such as increase in net inductance because of lead length, and decrease because of shielding, but those variables are independent of the coil itself...the error from the formula just adds to the other errors: construction tolerances, lead lengths, couplings to other metal. To keep total error to, say, 8%, we might well want a formula that gets us to within one percent, winding measurements that add a couple percent to that, and shielding and other "parasitics" that add another four or five percent. (Note that the 25mm diam x 25mm long coil suffers about a 5% inductance loss if it's in a 3" diameter shield...probably not too different from what coils see in shielded compartments in equipment.) If the formula has a seven percent error, I'd have little hope of building to within eight percent because of the other errors. I think formula accuracy is important for tiny coils, too, because with them, it's tougher to hold mechanical tolerances and you use up more of your error budget in the coil, leaving less error you can tolerate in the formula.

Thankfully, we do have formulas that are accurate enough.

Cheers,
Tom

2979. Shorty Forty

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-29 18:47:41 UTC
From: pgardella@yahoo.com
Message-ID: <57d04feb.0111291047.6e1e6cbb@posting.google.com>
Source record: 153731

I'm trying to build a shorty forty antenna (center fed inductively loaded dipole). I've got the ARRL antenna book, and several web sites with instructions. However they all refer to using a 2 1/2" diameter PVC pipe to wrap the coils on. Around here, the cheapest I can get 2 1/2" PVC is to special order it for $60. I supposedly only need 5" of it.

So my question is, could I use 2" or 3" PVC (standard sizes), and how would that effect the number of turns, if at all?

Thank you!

Patrick

Actually I thought it was a great reply, Put a smile on my face :)

Im a typical ham too :)

Saw some good heavy duty mounts right on the net. In fact try
the Bugcatcher home page. Might be couple there you could
scrounge together pretty easy and CHEAP (If ya know a welder)

If you download the free EZNEC demo program from http://eznec.com, there's a tutorial called the "Test Drive" that takes you through the design of some simple antennas, step by step. In EZNEC, you can find the Test Drive by clicking Help, then Contents. The Test Drive is one of the major sections listed. I suggest also reading the Getting Started section.

Doc

I dont know exactly how they are made, if mine ever goes belly up
I'll hacksaw the thing in 2 and see. They have been around for more
than a few years, I have had mine for close to 10 years. I suspect they
are more or less a plain balun (9to1) but they are not made for xmitting.
They do match the impedance of the longwire (about 500 ohms) to the
co ax/ radio and they do work very well. Ive done side by side comparisons
of the same antenna with and without the balun in place and using it will
increase most signals 2-3 s units and in some cases do better than that.
They are described as a very low loss magnetic transfer of energy. Using
a MLB you dont need an antenna tuner, Ive tried using one with it and
it doesnt seem to make much if any difference. I believe in the KISS principal
(keep it simple stupid) and the MLB works extremely well for me, I wont
ever have up a longwire with out it. Besides the impedance matching it
isolates the longwire from your radio. Ever have a 100' long wire up in
the winter with 30-40mph wind? remember the static shock that could
just about knock you on your behind? You wont have that with the MLB.
Less noisy too.

Patrick,
Sure, you can use a coil of a different diameter.
It will affect the number of turns in the coil, but
probably not by a whole lot. (Smaller coil = more
turns, larger coil = less turns.)

Source record: 153736

This looks like a good place to make a few general comments about comparing antennas.

1. When comparing antennas, do it when receiving. Set up a simple switch so you can switch between antennas. Compare signals from varying distances and varying directions. Watch each signal for a while to get a feeling for the QSB. To get quantitative comparison information, build a simple step attenuator and switch attenuation into the stronger antenna until both are equal. Or use the step attenuator to calibrate your S meter. Assuming that both antennas are reasonably matched, the difference on receive will be the same as on transmit.

2. There are several important reasons for doing receive tests instead of transmit tests. One is the unreliability of others' reports. Tom, W8JI, has run experiments comparing two antennas, and gotten rather dramatic reported differences -- when "antenna A" and "antenna B" are really the same antenna. (Try it yourself!) If you name the antennas, it's almost certain that the fancier sounding one will get the best reports ("appellation gain"). When comparing antennas with different polarization, for example a vertical with a broadside dipole, or a turnstile with a dipole off the end, polarization shift can cause large and varying differences. I've seen a dipole beat a vertical by 20 or 30 dB. Another measurement made a minute or so later showed the vertical beating the dipole by the same amount. By listening for long periods, you can see this happen and take it into account, but asking another station for a quick report is equally likely to show either antenna much better than the other. No one will be able to discern a couple or few dB of difference when the QSB is running 30 dB due to polarization shift. Finally, there's no way of knowing how many dB the other station's "S unit" is. It might be 5 or 6 dB, or it might be 2 or less. That's a big difference, especially if several S units are involved.

3. If you do use the S meter, make sure you're on the same band and with the same attenuator and RF gain control settings you used when calibrating it. Many S meters are nowhere near 6 dB per unit, so there's no way you can get any meaningful quantitative information from one without calibration. Assuming "about" 6 dB per S unit can result in values that are way, way off.

4. It's nearly impossible for a lot of people to make valid comparisons on the lower frequency bands, because antennas have to be separated so far to avoid interaction. Comparing coupled antennas doesn't give you any useful information -- when you take down the "worse" antenna, the "better" one might degrade. And the "worse" one might have been made worse when you constructed the "better" one.

5. Remember, there are only two ways for any antenna to have gain over any other. One is efficiency, and the other is by concentrating the energy in some directions in favor of others. So if both antennas are about equally efficient, and one is better in some azimuth or elevation directions, the other has to be better in others. The higher the gain, the narrower the angle. For example, compare a 20 meter dipole up 30 feet with an extended double zepp (EDZ) at the same height, at a 30 degree elevation angle. The EDZ has more gain than the dipole only over an azimuth range of about 90 degrees out of the whole 360 degree range. That means, if you listened to signals from random directions, the dipole would beat the EDZ in 3 out of 4 cases. Not only that, but there are directions where the dipole will be more than 10 dB better than the EDZ, and no direction (in theory) where the EDZ will be more than about 3 dB better than the dipole. I say "in theory", because nulls and distortions can occur in either pattern due to the local environment, resulting in directions in which either antenna could be dramatically better than the other. You might conclude from your tests that the dipole is a better antenna than the EDZ. Well, actually, if you want to talk to people in all directions, it is.

2985. "Egg-type" insulators, where can I buy them?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-29 20:30:06 UTC
From: vtail@hotmail.com
Message-ID: <3c0699bf.67179026@news.netis.com>
Source record: 153741

I've been out of ham radio for about 10 years, and am just now getting back in.

One of the things I need for my antenna installation is some egg-type insulators. You know, the ones, often used for breaking up guy wires, where you loop the wires through the insulator in such a way that if the insulator breaks, the wires are still looped together and whatever you're supporting (tower, mast, etc.) won't come crashing down.

I've asked at two Radio Shacks and at the local Ham Radio Outlet store, and everyone looks at me like I'm from the second moon of Jupiter. They don't even know what the hell I'm talking about!

I would have thought these things would be very comon.

Anyone have any idea where I can buy them on the web?

Thanks...

From what it sounds like, it is merely a tightly coupled link.
That should work relatively well, if the ground was reasonable.
I would expect it to work better if a series LC tuner was used
above the antenna side of the balun, to provide tuning of the
antenna. Old marine radio sets used that sort of coupling,
although it was not through a ferrite coupler. The balun is
not really a balun, in the purest sense, used this way, but
just a tightly coupled link. That would be my take of it.

From what you are saying about this thing, its not a balun. I think it's a broad band transformer. All versions of baluns have DC continuity. A 9 to 1 balun would take several cores to do but a transformer wound on a cup core or the like would be small and cheap to do. I've made such things myself, It's not hard. The name they gave the thing has only one "miss truth" it is in no way a "balun".

Nah, not lucky, just tried and true practicality. I have been using such
end fed antennae for over 30 years, all bands, and they usually always
outperform the average dipole. Such an antenna dates back to the earliest
spark era. Tried, true, and eminently practical, but not the usual ham
dipole thing everyone is want to run. Random wires have thier quirks,
though, but when tamed, make great and simple antennas. When set up
right, you don't need an SWR bridge, just an RF output meter. Max on the
RF meter and you are matched and loaded for bear. Improperly set up,
tho, and the floating RF can give you fits! (:+}}...

Hi all,

I just got my Technician's class license yesterday and have a ft-50r that I would like to use in my pickup truck. I need an external antenna for 2m and 70cm.

I am totally clueless as to what to buy. I read that through the glass isn't the best set up and I am thinking that locating it away from engine compartment might be a good idea. I have noticed that broadcast AM radio always seemed to have less ignition noise in a car with a rear mount antenna. Maybe a co-incidence but I have seen it too many times.

So recommendations on a good model for use on a truck that isn't too expensive (plant closed/out of work) would be helpful.

I also don't know the good places to shop via mail order so a few that have good reputations for delivering on time would also be nice.

Thanks,
Wes Szumera

I've had one for about a month now, and it works great, using it with a 2m Kenwood 261a. It's sitting in a 2nd floor closet as a matter of fact on a simple stand I made from PVC pipe. On 10 watts, I can reach repeaters within 20 miles full quieting, and can reach repeaters 50 miles away on 50 watts. Nice little antenna for $40 shipped in my opinion.

Regards,

Van

Hello All!
Is there a way on suspending ladder line horizontally for a span of about 50 feet? I thought I read somewhere where you could thread a rope to keep it from flopping in the wind? Anyone tried this or have any other ideas? Maybe its not necessary, but I think the SWR might change as the wire swings in the wind.
Thanks,
Terry

Well, you could take two 50 foot rolls of 1/2 inch copper tubing,
spaced every few feet, mounted on short masts, separated by some
sort of acrylic spacer, for the horizontal section, spaced to 450ish
ohms. That would require support at maybe 10 foot intervals. Clip
your feedline on each end, as needed. Overkill, but works. (:+}}...

I just used some light nylon braided line to pull it mostly taught
here and there. Worked fine. It is really not THAT critical in
amateur use.

Wish to thank the gentlemen (as well as those who may not be<G>) for confirming there is nothing significantly new for this issue, and that we are indeed still doing the same things we were doing in 1956.

I suspect - but do not know - that whatever convenience refinements have been marketed in the repackaged old designs, are basically aimed at today's higher-power scene that can tolerate the same old losses better but with more convenient tuning. FWIW we were using cheap surplus flexible shafts in 1956 to do exactly what a "screwdriver" does today as well (though the results certainly depended upon the skill & care of the brewer). However, some of us are still interesting in ancient low-power AM mobile rigs - and it looks like we may expect about the same propagation we achieved back then, and/or may as well build the same things. Actually, though unfortunate for propagation, this does have a kind of a timeless charm to it...

Sounds like about the same value I got when I was modeling a square 6m horizontal loop antenna using EZNEC. When I made a quickie model, using 12 gage wire taped to a cardboard box to hold the wire in place, I found the feed point was closer to 12 ohms per my MFJ antenna analyzer. So instead of screwing around with a Gamma match, or a Hair Pin match, I used two paralleled 1/4 wl sections of RG-58 coax for an effective 25 ohm 1/4 wave matching section. The finished antenna was adjusted to resonance by simply adjusting the ends of the element opposite the feed point for lowest SWR at the center of the bandwidth I wanted to work on. The SWR worked out to be about 1.1 at the center, and the measured 1.5 : 1 SWR bandwidth was around 450 KHz, which seems to be about the same as you get using the other two methods, but without any capacitors, coils etc. to mess around with.

Terry,
Most 'ladder line' will support it's own weight for 50 feet. To
keep it from 'flopping' around a lot, give it a couple dozen 'twists',
making it look like a spiral. Doesn't move around near as much...
'Doc

Jeff,
Sounds like we're talking apples and oranges. What you
have is NOT a balun, a 'link' coupler maybe, but just NOT
what the 'name' says it is. Shades of the old "Maxrad"(?)/
"Maxcom"(?) coupler. (encapsulated 50 ohm resister, rememebr
that one?)

The devil lies in that last sentence. That impedance is only correct at
a couple of frequencies. By the same token, I bet the random-wire would
work better at certain other freqs without the
xfmr/balun/MLB/whatchamacallit.

SWLs like 9:1 transformation because the majority of freqs will present
high impedance with a random-wire and the xfmr gets it closer into the
ballpark for a coax feed/50-ohm radio...but at the expense of
mismatching the 'close to odd 1/4 wave multiples'.

Not a substitute for a tuner, but for e-z broadband improvement, they do
the job.

-Bill

My Stars!

I'd buy a piece of 2" from Home Depot. It won't make that much difference, only affecting, most likely, the number of turns on the coil.
